Composite Estimate of Plasma and Red Blood Cell Volumes From 28 Studies of Pregnant and Nonpregnant Patients (1938-1963)¹⁰

Volume	Nonpregnant	Pregnant			
		20 wk.	30 wk.	34 wk.	40 wk.
Plasma, ml.	2,600	3,150	3,750	3,830	3,600
Red Blood Cell, ml.	1,400	1,450	1,550	1,600	1,650
Total Blood Volume, ml.	4,000	4,600	5,300	5,430	5,250

little by pregnancy and probably contains the same amount of hemoglobin as in the nonpregnant state. However, because the increase in plasma volume is relatively greater than the increase in red-cell volume, the hemoglobin concentration falls. The leukocyte count begins increasing at approximately the eighth week and gradually reaches its peak of 10,000 to 15,000 per cubic millimeter at term. In general, concentrations of electrolytes fall, the decrease being approximately 5 mEq. per liter for both cations and anions.¹² The total concentration of serum proteins decreases sharply, mostly in early pregnancy and due chiefly to a decrease in the albumin fraction.¹³ The significance of this change is unknown. The erythrocyte sedimentation rate begins increasing by the twenty-fourth week, the average corrected figure at term being 30 ml. per hour; the significance of this change is also unknown.

Pulse Rate and Blood Pressure

Several studies of the average resting pulse rate in pregnancy indicate that the rate begins to increase in the first trimester and peaks at approximately 88 beats per minute during the thirty-fourth to thirty-sixth week. Thus there are more than 14,000 extra beats per day in the pregnant state. Values for systolic blood pressure remain essentially unchanged until term, when a slight rise is normally noted; diastolic pressure usually decreases in the first and second trimesters and rises again to normal at term. Venous pressure measured in the arms, as well as in the right atrium, remains unchanged. However, femoral venous pressure is somewhat increased, probably due to vena-caval compression by the enlarging uterus. Right ventricular pressure, pulmonary artery pressure, and pulmonary capillary (wedge) pressure remain unchanged throughout pregnancy.

Cardiac Output

Determination of cardiac output in pregnancy by the Fick principle is subject to large error. Studies to date, although at some variance, indicate that the cardiac output begins increasing in the third month,

reaches a peak of 30 to 40% above normal somewhere between the twenty-fifth and the twenty-eighth week, then gradually declines to near normal at term.¹⁰ The stroke volume also is increased in pregnancy, since cardiac output increases to a greater extent than does pulse rate.

Oxygen consumption begins to increase in the second month, peaking 10 to 20% above normal at term. This increase is due primarily to fetal and uterine metabolism. Since cardiac output increases in early pregnancy to a greater extent than does oxygen consumption, the arteriovenous difference is smaller until near term, when it again approaches normal.

The heart itself is displaced upward, forward, and laterally as pregnancy progresses; the point of maximal impulse is therefore felt in the fourth intercostal space at or to the left of the midclavicular line. Both S_1 at the apex and pulmonic S_2 at the base are accentuated. A systolic murmur, frequent premature ventricular contractions, and split heart sounds are common. Several roentgenographic studies indicate that the mean heart volume increases 10 to 15% between the first and the third trimester; but the significance of this observation — if indeed it is valid — is not known. In pregnancy the electrocardiogram shows a left axis deviation until late in the third trimester, when it may shift back toward the right. Other cardiographic changes occasionally noted in the various leads include flat or inverted T waves, deep Q waves, depression of ST segment, and low QRS voltage.

Pulmonary Vascular Bed

Changes in the pulmonary vascular bed increase the lung markings on chest roentgenograms. As the uterus enlarges and encroaches on the diaphragm, fine basilar rales may be noted. Decreased height of the thoracic cavity is compensated for by an increase in its anteroposterior and transverse diameters. Pregnancy causes no significant alterations in the profile of the lung volume: vital capacity and maximal breathing capacity remain unchanged; during the third

Continued

trimester, the functional residual capacity decreases slightly, but the decrease is compensated for by an increase in the inspiratory capacity. The dyspnea of pregnancy noted in the first and second trimesters by so many women without heart disease is probably related to overbreathing, with subsequent drop in $p\text{CO}_2$.¹⁴

Standard exercise tolerance tests throughout pregnancy in normal women as well as in those with mild heart disease fail to prove that pregnancy imposes an added burden to physical activity.

Adams,¹⁵ and Adams and Alexander,¹⁶ and Hendricks¹⁷ in their studies on hemodynamics in labor agree that during a contraction the cardiac output rises 20 to 30% and that the pulse and the blood pressure increase — left ventricular work therefore is increased, and that from 250 to 500 ml. of blood is extruded from the uterus. They further have stated that there is no cumulative effect through the three stages of labor and that pain and anxiety in part, or perhaps wholly, account for the changes observed. At the conclusion of the third stage both cardiac output and left ventricular work were found to be significantly increased over those recorded during the first and second stages; this was considered to be due to increased venous return.

Diagnosis

A few diagnostic pitfalls may be encountered in the cardiac patient who is pregnant; these pitfalls are represented by the development of a new disorder such as acute rheumatic fever or subacute bacterial endocarditis, or as congestive heart failure superimposed on the existing heart disease.

In a previously unexamined patient, the task of diagnosing heart disease may be somewhat confusing. A complete history must be taken, the physician keeping in mind the normal physiologic changes of pregnancy. On physical examination a heart murmur is the most frequently encountered problem. Gorenberg and Chesley¹⁸ go so far as to say that a systolic murmur may be found in every pregnant woman if she is examined often enough. The criteria of Burwell and Metcalfe⁵ are adhered to by many

when an attempt to distinguish the functional murmur from organic heart disease is made:

1. The presence of a diastolic murmur must be regarded as clear evidence of organic disease.
2. Unequivocal cardiomegaly, as shown by roentgen examination, is an acceptable sign of organic disease but seldom exists as the only sign.
3. The presence of a systolic murmur of grade 3 intensity or greater (on the basis of 6) usually indicates organic disease.
4. The presence of a severe arrhythmia, such as atrial fibrillation, atrial flutter, or complete heart block, always indicates organic disease.
5. Other unequivocal signs include a pericardial friction rub, true angina pectoris, a diastolic gallop rhythm, or a pulsus alterans, persistent bacteremia, and notching of the lower rib margins on a chest roentgenogram.

Ancillary studies may include anteroposterior, oblique, and lateral roentgenograms of the heart after barium swallow (if indicated), electrocardiogram, pulmonary function studies, venous pressure and circulation time, exercise tolerance tests, and even cardiac catheterization in those women who urgently require clarification to ensure proper management.

Management

In the management of the pregnant cardiac patient, three possible solutions present themselves. The first is interruption of the pregnancy — that is, therapeutic abortion. The second is improvement of the heart condition through surgery, and the third is medical management of the cardiac problem throughout pregnancy, labor, and the puerperium.

Management as well as prognosis in most clinics is based on the patient's performance in previous pregnancies and on her functional capacity prior to her present pregnancy according to the criteria of the New York Heart Association¹:

Class I patients are those with cardiac disease but without resulting limitation of physical activity. For them, ordinary activity

does not cause undue fatigue, palpitation, dyspnea, or angina.

Class II patients have cardiac disease that results in slight limitation of physical activity. Such patients are comfortable at rest, but ordinary activity results in fatigue, palpitation, or angina.

Class III patients have cardiac disease that causes marked limitation of physical activity. They are comfortable at rest, but less than ordinary activity causes fatigue, palpitation, dyspnea, or angina.

Class IV patients have cardiac disease that makes it impossible for them to carry on any physical activity without discomfort. Symptoms of cardiac insufficiency are present even at rest. Any physical activity undertaken increases discomfort.

Therapeutic Abortion

There is some philosophic variance of opinion among those who have had experience with large numbers of pregnant cardiac patients.

Mendelson⁶ has stated the belief that the procedure is justified in the face of serious cardiac incapacity not amenable to surgery; however, he is willing to rely on supportive measures when religious or other special considerations are involved. Burwell and Metcalfe⁵ have recommended interruption of pregnancy only after careful study of the individual problem. They not only take into account the severity of the heart disease but also consider the special significance of a given pregnancy to a given patient. Rovinsky and Guttmacher⁷ strongly recommend therapeutic abortion for class IV patients, but believe that class II and III patients generally are better off completing the pregnancy. They too individualize their treatment somewhat.

In regard to rheumatic heart disease, Gorenberg and Chesley¹⁹ have stated that "if a patient . . . is seen early enough in pregnancy to be aborted therapeutically, she has been seen early enough to be given good prenatal care and thus be allowed to complete a successful pregnancy." Lund²⁰ has said that *therapeutic abortion is rarely, if ever, indicated* and should not be considered

until there is persistent or progressive disability after thorough, effective medical or surgical treatment or both. Gerbie and Skom²¹ are of the same opinion. They pointed out: "If the heart is in failure, interruption of pregnancy cannot be safely performed, and if the heart is compensated, interruption of the pregnancy is usually not indicated."

Improvement of the Heart Condition Through Surgery

Rapid and dramatic advances in cardiac surgery within the past 15 years have made it possible to improve the heart condition through surgery.

Mitral stenosis is the most frequent specific defect present, and experience in the handling of this lesion is, therefore, greatest. There is agreement on the advisability of *mitral commissurotomy for mitral stenosis*, when indicated in the nongravid woman in her childbearing years, because the burden of subsequent pregnancies usually is tolerated much better. But there is again some philosophic variance of opinion regarding the advisability of this procedure during pregnancy.

Surgeons and internists in general²²⁻²⁵ believe that commissurotomy is indicated in early gestation for heart failure or as an alternative to therapeutic abortion. Harken and Taylor²² prefer commissurotomy in patients who are borderline class III and IV, and they cite lower fetal and maternal mortality rates in operated patients, as contrasted to those managed medically. They also point out that therapeutic abortion done after commissurotomy, which is recommended by many, raises fetal mortality rate to 100%, subjects the patient to the risk of two operations, and is objectionable to many on religious grounds.

Mendelson⁶ has stated the belief that commissurotomy is indicated, if conception has already occurred, for patients with pure mitral stenosis and signs of pulmonary congestion. He favors cardiac surgery as soon after conception as possible so that the patient may benefit immediately, and so that there will be more time to resort to thera-

Continued

peutic abortion in the event of operative failure.

On the conservative side are Rovinsky and Guttmacher,⁷ Burwell and Metcalfe,⁵ and Gerbie and Skom.²¹ They consider commissurotomy for those patients who have severe intractable pulmonary congestion or edema early in pregnancy and who refuse interruption, or for those patients who after the fourth month are in heart failure or have pulmonary edema in spite of vigorous medical management. These authors point out that commissurotomy during pregnancy does not eliminate the hazard of rheumatic heart disease to mother and fetus in the present or in future pregnancies, that present-day medical management is effective for all but a few patients, and that the postcommissurotomy syndrome, atrial fibrillation, or embolic phenomena may develop.

Mitral insufficiency and the aortic valvular lesions are much less common and, even when found in pregnancy in their pure form, seldom cause trouble. Surgical repair imposes a far greater risk than does mitral commissurotomy, because it involves open-heart surgery with the use of cardiopulmonary bypass and usually involves insertion of a prosthesis. There is at least one case reported of Hufnagel valve replacement for severe aortic insufficiency that was followed by conception and a normal successful delivery by cesarean section.²⁶ The surgical mortality rate is 15 to 25%, however.

Often patients with severe congenital heart disease do not reach childbearing age; if they do, they rarely marry and have children. When successful corrective surgery has been undertaken prior to pregnancy, few problems are encountered. But the advisability of corrective surgery during gestation depends on personal opinion, the type of lesion, and primarily on its severity. Mendelson⁶ has stated that whenever indicated (that is, in severe uncontrollable failure, operable defect, reasonable risk) a repair during pregnancy should be undertaken prior to the peak cardiac load.

Ligation of a patent ductus arteriosus appears to carry the least risk but usually is not indicated unless uncontrollable heart

failure or subacute bacterial endocarditis develops. An atrial septal defect may be repaired during pregnancy but should probably be done only when heart failure cannot be medically controlled or when the patient declines therapeutic abortion. *Repair of a ventricular septal defect* is somewhat more risky, requiring open-heart technique. If the lesion is large and the danger of heart failure great, therapeutic abortion or medical management is recommended by Rovinsky and Guttmacher.⁷ They do not believe that there is any clear indication at the present time for correction of tetralogy of Fallot during pregnancy. Patients with pulmonic stenosis and aortic coarctation generally do well in pregnancy,²⁷ and unless progressive symptoms develop, surgery should probably be deferred until after delivery.

Medical Management

The medical management of the pregnant cardiac patient is based on two principles: the prevention of heart failure and its treatment, if failure should occur.

Prevention of heart failure revolves around reducing the avoidable work load on the heart. There are certain unavoidable loads placed on the heart of a pregnant woman that are maximal from approximately the twenty-eighth to the thirty-fourth week. This is, therefore, the critical period in the prevention of heart failure.

Restriction of physical activity is most important; Class I and II patients need not be greatly restricted but should have extra rest each day and should minimize house-keeping, stair climbing, emotional strain, and outside work. Class III patients require greater restriction, and Class IV patients must be kept at near complete rest in bed, either at home or in the hospital. For all classes, gain in weight should be kept to a minimum, especially in the obese, by low-calorie diets and low-sodium intake, the amounts determined more or less by consideration of class and clinical status.

Diuretics (thiazides) have assumed a major role in the management of the pregnant cardiac patient and are the mainstay of treatment for the pregnant woman with

hypertensive heart disease. Patients with moderate-to-advanced disease who show rapid or excessive gain in weight or evidence of venous congestion or fluid retention should receive orally administered diuretics. The use of parenterally administered diuretics, for example, meralluride, is indicated in acute or chronic heart failure during pregnancy.

Anemia adds to the circulatory load and should be treated promptly. Iron deficiency is the most common cause of the anemia; therefore large doses of iron, either orally or parenterally administered, are usually necessary. Careful transfusion of packed cells may be given to patients with severe anemia.

Since intercurrent infection is the most important precipitating cause of heart failure in the pregnant rheumatic patient, *antibiotic therapy is indicated at the first sign of infection*. Some clinics use prophylactic antibiotics throughout pregnancy in their rheumatic patients.

Hyperthyroidism can occur in pregnancy and is occasionally a factor leading to congestive failure. The possibility of hyperthyroidism should be kept in mind, for it is treatable by the use of antithyroid drugs or iodine or subtotal thyroidectomy. Radioactive iodine should not, of course, be used during pregnancy.

Congestive failure is most likely to occur when the cardiac load is maximal, that is, from the twenty-eighth through the thirty-fourth week. Lund²⁰ has stated: "Congestive failure is a medical and not a surgical disease and it should not be treated by cesarean section, hysterotomy, or induction of labor." Most authorities recommend immediate hospitalization and strict rest in bed if there is any indication of early heart failure, even a slight cough.

Digitalis is the most important drug in the treatment of heart failure and should be given whenever symptoms or signs of congestive failure appear during pregnancy. In the pregnant patient, digitalization should be carried out slowly over several days, but if necessary it may be done rapidly. This drug crosses the placental barrier, but

when used in therapeutic doses, it does not produce fetal distress. Maintenance therapy should be continued for class III patients but may be discontinued, with caution, in compensated class II women. Prophylactic digitalization of class II and III patients is practiced in some clinics for patients with a history of heart failure. Further treatment includes the measures previously enumerated for the prevention of congestive failure and may also call for the use of oxygen, morphine or meperidine, aminophylline, and rotating tourniquets or phlebotomy. One of the most serious complications of mitral stenosis in pregnancy is acute pulmonary edema. According to Mendelson,⁶ edema alone accounts for the greatest number of deaths of pregnant cardiac patients; it must therefore be treated promptly.

Labor and Delivery

It is now a well recognized principle that the pregnant cardiac *patient is best delivered vaginally*; if, however, an obstetric indication exists, *heart disease is only a relative contraindication to cesarean section*. The only exception concerns those patients with aortic coarctation. Some obstetricians believe that delivery in these cases is best accomplished by cesarean section. In the past, early induction of labor was commonly practiced; then cesarean section was considered the best means of delivery. Within the past 20 years, however, comparative studies have appeared that have indicated that vaginal delivery carries the least risk.^{5,6} Choice of anesthetic agent depends not only on the maternal and fetal status but also on the training and competency of the anesthesiologist. *Inhalation anesthesia probably is best* when conditions are ideal (good premedication, absence of respiratory disease, mature infant); but pudendal block or local infiltration may be the method of choice. Caudal and spinal blocks are effective but occasionally cause hypotension.

Hopefully, the cardiac patient beginning labor will be compensated; for this reason most clinics hospitalize their class II, III, and IV patients at least a few days before the estimated date of confinement, for reevaluation.

Continued

tion and treatment of their cardiac status. Antibiotics should be given prophylactically to rheumatic subjects, because there is often a transient bacteremia during labor.²³

As stated previously, the extra work imposed on the heart by labor has no cumulative effect, and the changes noted are considered to be primarily the result of excitement. In the first stage, therefore, good sedation should be maintained; the use of atropine and scopolamine is best avoided because each tends to produce, respectively, tachycardia and excitement. *A semireclining position for the patient is best.* The pulse and the blood pressure must be checked frequently; if the pulse rises above 110 beats per minute between contractions or if a cough, tachypnea, or dyspnea occurs, morphine and oxygen should be given and digitalization rapidly carried out. If the patient is not yet fully dilated when cardiac decompensation begins to occur, any means of effecting delivery will tend to aggravate the situation.

The second stage of labor should be shortened; or as Mendelson⁶ has said, "Prolonged straining to achieve the esoteric ecstasy of natural childbirth is not advocated. . . ." *Low forceps are advisable to shorten the second stage*, but extra care must be taken not to incur lacerations by application before dilatation is completed.

In the third stage *blood loss should be kept to a minimum* to avoid the secondary

strain of anemia. Large, intravenous infusions should be avoided; ergonovine should not be used because of its vasopressor effect; synthetic oxytocin is preferable due to its lack of vasopressor effect. Because immediate postpartum heart failure usually is caused by excessive blood loss, the treatment should include the Trendelenburg position and immediate and careful replacement of blood. Vasopressors should be used if blood loss does not seem to account for the heart failure. Occasionally, heart failure may occur between the fourth and the seventh postpartum day; the failure is associated with a delay in diuresis. Therefore, cardiac patients usually should be kept in the hospital at reduced activity for two weeks after delivery.

The so-called fourth trimester is the next dangerous period. A significant number of

Mendelson ⁶ (New York Lying-In Hosp.)	1960	0.8	31	20	0	4
Ehrenfeld and Associates ²⁹ (Hadassah U., Israel)	1964	1.13	4	0	4	0
Rovinsky and Guttmacher ⁷ (Mt. Sinai Hosp.)	1965	0.5	1	0	1	0

women experience heart failure during this period; failure is probably due to the burden of resuming household duties. The term "postpartum heart failure" refers to an ill-defined syndrome that begins two to 10 weeks after delivery and is characterized by generalized cardiomegaly, signs of heart failure, and thromboembolism in the absence of any history of heart disease. It is apparently an idiopathic or toxic degeneration of the myocardium leading to heart failure.

Prognosis

During the past 50 years, the maternal mortality rate for the cardiac patient has declined markedly, mainly as the result of improved medical management (Table 3). Good medical management, in turn, implies a certain amount of patient cooperation as well as a willingness on the physician's part to hospitalize the patient at the first sign of decompensation.

Increasing age in the rheumatic subject is accompanied by an increased incidence of heart failure. Generally, the pregnant cardiac patient who is more than 25 years old should be seen weekly, regardless of functional status. There are no definite data thus far which show that increasing parity is accompanied by an increased rate of heart failure. Gorenberg and Chesley,¹⁹ in their report on the long-range prognosis in severe rheumatics, found no evidence that later pregnancies increased the average annual death rate.

A history of congestive heart failure, particularly if the failure occurred during a pregnancy, forewarns the physician of heart failure in the present pregnancy. With strict medical management these patients frequently can be carried through their pregnancy without heart failure occurring.

Chronic atrial fibrillation, although rare in the woman of childbearing age, is a serious finding. It indicates rather severe

organic heart disease and predisposes the patient to congestive failure as well as embolic phenomena. Mendelson,⁶ in a collected series, reported a maternal mortality rate of 12% and a fetal mortality rate of 50%.

Functional classification assigned prior to pregnancy can give an important estimate of the patient's ability to go through pregnancy. Class I and II patients generally have a minimum of trouble, but class III and IV patients account for almost all the cases of congestive failure and death⁶ (Table 4).

Generally, the chances of fetal mortality are increased in women with heart disease that is severe enough to produce symptoms; the more severe the disease, the greater is the possibility of fetal mortality. Burwell and Metcalfe⁵ have reported a fetal mortality rate of 8% for class III patients and 21% for class IV patients; these figures exclude therapeutic abortions. The maternal factors associated with increased fetal loss include severe congestive heart failure, severe congenital heart defects, and chronic atrial fibrillation as well as serious underlying medical or obstetric complications or both.

Summary

Heart disease may be associated in approximately 3% of all pregnancies. Evaluation and management are based on an understanding of the normal physiologic changes of pregnancy. Although heart surgery or therapeutic abortion may be performed, most of these patients can be successfully guided through their pregnancy, labor, and postpartum period by careful medical management based on the prevention and treatment of congestive failure. The maternal mortality rate is low (1½ to 1%), and death occurs almost exclusively in classes III and IV.

Could it be
something
more than
growing
old that
“gets her
down”?

Mild mood depression, poor appetite, little interest in the present or future. Does this picture mean that she's giving in to functional fatigue?

When functional fatigue is part of her problem, Alertonic can help counteract accompanying apathy and inertia. It helps lift mood, stimulate appetite, and establish new interest in daily life.

Pleasant-tasting Alertonic combines pipradrol hydrochloride—a gentle cerebral stimulant—with an excellent vitamin and mineral formula, in a satisfying 15% alcohol vehicle.

Especially in the aging patient, nothing fosters confidence and a sense of well-being better than your own personal warmth, understanding, and encouragement. Between visits, however, your prescription for Alertonic can help keep your patient from giving in to functional fatigue.

Adequate dosage is important: Prescribe Alertonic—one tablespoonful t.i.d., 30 minutes before meals ...tastes best chilled.

And for your patient's sake, prescribe Alertonic in the convenient, economical one-pint bottle.

Available only on prescription
Alertonic[®]

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%, pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B₁) (10 MDR*), 10 mg.; riboflavin (vitamin B₂) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B₆), 1 mg.; niacinamide (5 MDR), 50 mg.; choline,† 100 mg.; inositol,† 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.

†The need for these substances in human nutrition has not been established.

Indications: 1. Functional fatigue such as that often associated with: a depressing experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive compulsive states.

Side effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

She doesn't feel she "suffers" from hypertension

**Butiserpazide® lowers blood pressure
so smoothly that patients are often untroubled
by either disease or therapy**

By switching patients to BUTISERPAZIDE you may be able to free them of much of the burden of hypertension. Clinical comparisons have shown that many respond with (1) smooth, uniform lowering of blood pressure¹...at times to levels *below* those attained with previous therapy²; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness²; plus

(3) "...lowered incidence of drug side effects."²

And there's an added advantage: the usual dosage is just 1 tablet once or twice daily, often without need for supplementary therapy. (BUTISERPAZIDE provides not only hypotensive and diuretic action, but a mildly sedative effect as well.) Isn't this the way to take the suffering out of hypertension?

You have a choice of 2 strengths:

Butiserpazide®-25

Prestabs®* Tablets

in mild to moderate cases, often effective at half the usual thiazide or thiazide/reserpine dosage.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 25 mg. (¾ gr.); Reserpine 0.1 mg.

Butiserpazide®-50

Prestabs®* Tablets

controls many moderate to severe cases without any need for ganglionic blockers, or other more potent agents; if such agents are needed, their dosage can be cut in half.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 50 mg. (¾ gr.); Reserpine 0.1 mg.

*15 mg. of Butisol (butabarbital), plus the other ingredients, in outer layer; 15 mg. of Butisol (butabarbital) in a specially coated core for delayed action, to approximately equalize duration of action for all components.

Contraindicated in presence of renal impairment, peptic ulcer, ulcerative colitis, or mental depression, and in patients with porphyria or those sensitive to any component. **Warning:** Coated potassium tablets, sometimes administered in conjunction with anti-hypertensive therapy, may be associated with small bowel lesions which have led to obstruction hemorrhage, and perforation. Surgery has been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occur. **Precautions:** Exercise caution in hepatic disease, diabetes, surgery, coronary artery disease, epilepsy, E.S.T., and in patients receiving digitalis. **Side Effects:** Electrolyte imbalance, hyponatremia, hypochloremic alkalosis and/or hypokalemia, hyper-

uricemia and gout, bradycardia, drowsiness, skin rashes, hangover, systemic disturbances, weakness, leg cramps, diarrhea, epistaxis, dizziness, urticaria, dry itching skin, nausea, vomiting, palpitation, superficial skin bruises, headache, dehydration, paresthesias, photosensitivity, pancreatitis, jaundice, xanthopsia, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, nasal congestion, hypotension, lassitude, loose stools, anorexia, bizarre dreams, peptic ulcer, ulcerative colitis, mental depression. (Ammonium chloride, which may be administered to reverse hypochloremic alkalosis, should not be given to patients with hepatic disease.) **Before prescribing or administering, see package insert.** †Warning: May be habit forming. **Usual Adult Dosage:** Butiserpazide®-25 or Butiserpazide®-50: 1 tablet daily or b.i.d. **References:** 1. Johnson, H. J., Jr.: *Penna. M. J.*: 67:35, 1964. 2. Coodley, E. L.: *Curr. Ther. Res.* 4:460, 1962.

McNEIL

McNEIL LABORATORIES, INC.,
FORT WASHINGTON, PA.

Why Western Electric rewired its safety program to include training in defensive driving. And why you should too.

Last year, American industry lost over 22,000 trained employees killed in off-the-job traffic accidents. And 1½ billion dollars in lost time and production. But, hundreds of companies—big and small—are doing something about it. Like Western Electric. In the last two years, Western Electric trained 800 employees with the National Safety Council's Defensive Driving Course. And hundreds more are

signed up to take this complete course in new and tested concepts and techniques of defensive driving. You can do the same thing for the employees of your plant, office or facility. The National Safety Council will be glad to tell you how to set up the Defensive Driving Course in your company. And reduce traffic accidents among your employees *significantly*. Mail the coupon today.

Hystero-graphy

A New Aid in Diagnosis of Hydatidiform Mole

THE DIAGNOSIS of a hydatidiform mole prior to the actual passage of molar tissue remains a perplexing and often frustrating problem. Rapidly increasing uterine size, absence of the fetus on abdominal x-rays, markedly elevated chorionic gonadotropin titers, vaginal bleeding and premature symptoms of toxemia suggest the presence of this tumor.

The unobstructed passage of a probe through cervical canal well into the uterine cavity has been considered by many to be the ultimate definitive diagnostic procedure. The hazards of the "probe test" to a normal intrauterine pregnancy are obvious.

Torres and Pelegrena recently described transabdominal intrauterine contrast medium injection as a safe and accurate diagnostic technique. This procedure was used in evaluating the following patient.

Case Report

This 23-year-old white gravida II para I was first seen in the office October 18, 1966. Her last menstrual period had been August 18, 1966. She had delivered a full term male infant June 14, 1964. Physical examination was essentially normal. The uterus was approximately three times normal size. The microhematocrit was 40.

She first noted scanty, brown vaginal discharge October 25, 1966. One week later an episode of moderately profuse vaginal bleeding occurred. She was then hospitalized. Her uterus had now enlarged to a point midway between the pubis and the umbilicus. The cervix was thick and closed. No tissue had been passed. The hematocrit was 36. The chest x-ray was reported to be normal. A twenty-four-hour urine gonadotropin level was reported as "greater than 325,000 i.u. and less than 487,000 i.u./24 hours; in the high normal range." The patient was dismissed from the hospital and arrangements were made to see her frequently in the office.

Intermittent vaginal bleeding continued. On November 28, 1966, the uterus was enlarged to the level of the umbilicus. No fetal heart tones were heard. The microhematocrit was 33. Urinalysis revealed 1+ albuminuria. A probe was gently passed through the cervical canal to a depth of four inches without meeting resistance.

The patient was re-hospitalized. The following day her abdomen was surgically prepared and draped. The procedure was then monitored with image intensified fluoroscopy with the television projection. A scout film revealed no evidence of a fetus. Following local infiltration with 1% Carbocaine a No. 18 spinal needle was introduced transabdominally in the midline 3 to 5 cm. below the umbilicus into what was thought to be the uterine cavity. Aspiration was not productive of blood or amniotic fluid. Several cc. of a test dosage were injected, then rapidly 50 cc. of Hypaque. Fluoroscopy revealed the typical "moth-eaten or honey-combed pattern (See Figures 1 and 2) considered to be unquestionable radiographic evidence of a hydatidiform mole."

Continued

Figure 1

Figure 2

The injection was repeated in approximately thirty minutes because we were not prepared for the almost instantaneous absorption and renal excretion of the dye. The characteristic pattern again appeared.

That evening the patient spontaneously passed 545 grams of clots and typical grape-like molar tissue. A dilation and curettage were done the next morning, with removal of more molar tissue. Prior to hospital discharge the patient was given a prescription for an ovulation-inhibiting drug. Pregnancy tests during the subsequent two weeks have been negative.

Summary

The described technique proved to be therapeutic as well as diagnostic in this case. It is the author's cautious impression that perhaps the hystero-gram, using proper precautions including the injection of a maximum of 50 cc. of opaque material, is less hazardous and more illuminating than the "probe" test in the diagnosis of a hydatidiform mole.

For Smallpox

A medical student, Thomas Dover, residing in Thomas Sydenham's house, had the smallpox — and later he told how the master treated him: 'First I was bled to the extent of twenty-two ounces; then an emetic. I had no fire allowed in my room, my windows were constantly open, my bed-clothes were ordered to be laid no higher than my waist. He made me take twelve bottles of small beer, acidulated with spirit of vitriol, every twenty-four hours.'*

The Physician's Workshop

Needle Biopsy

Use of the Schleicher Tissue Core Instrument

THE SCHLEICHER TISSUE Core Instrument,¹ originally designed for bone marrow biopsy, is a practical tool for obtaining undistorted tissue from other organs. The commonly used biopsy instruments may tear, compress, or break up the specimen because suction has to be applied to sever the tissue from the organ. These artefacts* make it difficult to evaluate the histology. In addition, the instruments are complicated, easily damaged, and costly. The Schleicher tissue core instrument is well designed, sturdy, inexpensive, and easy to use.

The Instrument

The Schleicher tissue core instrument is available in four gauges: 13, 15, 17, and 19. The total length of the instrument with the core shaft hub attached is 13 cm. The core shaft measures 11.5 cm.** and has a conical razor-sharp bevel that cuts smoothly through soft tissue. Situated above the bevel is a 1-cm. straight slot and an air hole. A pointed stylet and a flat end obturator complete the unit. The instrument is shown in Figure 1. (See next page.)

Technique

The skin is sterilized and anesthetized. A small incision is made into the skin over the organ to be biopsied. The cutting edge of the core shaft bevel is lined up with the base of the stylet point. The core shaft is tightly secured in the hub by the set screw. The instrument is held as shown in Figure 2 (next page). The core shaft with the stylet in place is advanced through the incision into the organ, penetrating it for a distance of one to two millimeters. The stylet is then withdrawn. Slight pressure is applied while slowly rotating the instrument clockwise. When a core of about 3 to 4 mm. has been cut, a slight resistance is felt. If a longer specimen is wanted pressure is increased.

Severing the Tissue Core

Before withdrawing the instrument, the bevel is moved about 1 mm. up, down, or sideways in order to sever the core from the organ. The instrument is now rapidly rotated several times and withdrawn. The straight slot allows inspection of the specimen. Tissue cores of 1 cm. are readily obtained without distortion of the histology.

Expelling the Core

A solid tissue core can be expelled immediately with the flat end ob-

Continued

**Core shafts of any length and the instrument can be obtained from the manufacturer Becton, Dickinson and Company, Rutherford, New Jersey 07070.

turator. To prevent the core from bulging into the slot opening, a finger or a transparent plastic tubing is placed over the slot. The specimen is immediately immersed in formol-saline fixing fluid* (See footnote at bottom of next page) and allowed to harden for one hour.

If the core is too fragile to expel, the specimen is left in the shaft, which is disengaged from the hub by loosening the set screw. The shaft is placed in the fixing fluid for one hour. The slot and the air hole permit the fluid to come in contact with the tissue core. The tissue core

Fig. 2 — The assembled Schleicher Tissue Core Instrument in situ. The pointed stylet is withdrawn when the organ has penetrated about one to two millimeters.

NEEDLE BIOPSY

contracts slightly with fixation and can be readily expelled for further hardening.

Processing the Core

If a core contains calcium, the specimen is placed, after the initial fixation, into a decalcifying solution** for one-half to one hour. It is washed in tap water for a few minutes and placed in 80 per cent alcohol until ready for processing. A properly fixed and decalcified tissue core can be handled routinely in the histology laboratory.

When a tissue core is taken during surgery the bevel of the core shaft without the stylet is placed directly on the surface of the organ and the specimen obtained as described above.

Testing the Core Shaft Bevel

The razor sharpness of the core shaft bevel can be tested by rotating and slightly pressing the cutting edge against a few layers of cleansing

paper. A sharp edge readily cuts smooth-bordered discs which are retained in the lumen of the core shaft. Sharpness of the cutting edge is restored by moving the bevel across a No. 000 emery paper.

Comments

Using the procedure as outlined we have procured forty-five tissue cores from various organs with the Schleicher tissue core instrument. All specimens have been of good quality. Biopsy sites include breast, liver, thyroid, lymph nodes, and skin. Figures 3, 5, and 6 show core histologic preparations of a skin nodule, thyroid, and liver obtained with the 15-gauge, and Figure 4 of a breast biopsy procured with the 13-gauge instrument. The 13-gauge core shaft is preferred by us for breast biopsy and for tissue cores taken during surgery. Diagnostic specimens have been obtained, however, with the 15, 17, and 19-gauge instrument.

Summary

The Schleicher tissue core instrument is ideally suited for obtaining a specimen for biopsy from soft organs other than the bone marrow. The technique is described.

The tissue core cut by the razor-sharp bevel preserves the architecture of the tissue. Because the specimen may be fixed within the lumen of the core shaft, artefacts are minimal. Forty-five tissue cores have been procured from various organs; all specimens have been of good quality.

Vesicoureteral Reflux in Children*

A Brief Review

THIS IS INTENDED to be an impartial review rather than a defense of a particular thesis. It is based upon personal experience, observation, and rather wide reading.

The Ureterovesical Junction

It has been demonstrated conclusively by many observers that passage of urine up the ureters is an abnormal phenomenon in man. It is said to be prevented by the obliquity of the intramural and particularly of the submucosal ureter (Figure 1). The latter is compressed as the intravesical pressure rises during urination. Since the trigone contracts during urination to pull open the internal meatus, Hutch believes that this same contraction also lengthens and flattens the submucosal ureter, thus supplementing the antireflux effect of the intravesical pressure. Normal ureteral peristalsis also exerts a protective action, as evidenced by Figure 2. This urogram was made 12 years after a Boari operation, which involves no attempt to mimic the ureterovesical valve.

The Deleterious Effects of Reflux

Vesicoureteral reflux can injure the upper urinary tract in four ways: (1) It subjects the ureters and kidneys to the voiding pressure, which greatly exceeds that normally prevailing in the ureters and kidneys. If unchecked, this leads to dilatation and later thinning, at first of the ureters and later of the renal pelves, finally with hydronephrotic atrophy and impaired renal function. Any obstruction to urination aggravates these effects by raising the voiding pressure. (2) Any increase in the ureteral lumen di-

minishes the effectiveness of peristalsis, and thinning of the ureteral wall reduces its force, thus enhancing the untoward consequences of reflux by inducing secondary stasis of urine. (3) Bacteria in the bladder may be propelled to the kidneys. (4) Much of the regurgitated urine descends to the bladder immediately after voiding has reduced the intravesical pressure, so that there is residual urine whether there is obstruction to urination or not. This defeats the "washing effect" of micturition which Cox and Hinman believe to be essential in eliminating bacteria from the bladder.

Historical Highlights

Although Hutch in 1952 was apparently the first to try to eliminate existing reflux surgically, its occurrence and most of its causes had been known for a great many years. The attitude of urologists toward reflux before 1952 suggests Mark Twain's remark about the weather — "everyone talks about it, but no one does anything about it." Galen (about 150 A.D.) is said to have found that he could not squeeze urine from the dog's bladder into his ureters (Polk). DaVinci sketched the oblique course of the ureters through the vesical wall in the 15th century (Belt). Zemblinoff in 1883 observed reflux in the anesthetized rabbit, an observation verified in 1893 by Lewin and Goldschmidt, who also commented that the phenomenon was rare in the dog because his bladder was thicker and his ureterovesical junctions more oblique than those of the rabbit. Harrison had already (1884) declared that reflux in man was abnormal because of this obliquity.

The disorder has been produced experi-

Fig. 1 — The bladder and ureterovesical junction.

mentally by slitting the roof of the submucosal and intramural ureters (Andler 1925 and Gruber 1929); by lumbar sympathectomy (Tanagho and Hutch); by pelvic neurectomy (Torbey and Leadbetter); by cross cutting the trigone just below the ureteral orifice (Hutch); and by implanting pellets of sterile paraffin into the bladder and later infecting them (Sommer and Roberts).

Kelly in 1899 had seen air bubbles issue from the ureters during air endoscopy; Alksne (1908) had a patient void through a post nephrectomy ureteral stump. In 1924 Bumpus found reflux in 8.6 per cent of 1036 cystograms, chiefly in adults, and attributed it to infection, including tuberculosis, to neurogenic vesical dysfunction, and to operations upon the bladder. Schmidt (1927) stated that irritating contrast agents could cause it, and a year later Blum spoke of "anomalies of the valves." Brattstrom found a straw in the renal pelvis, while others reported such oddments as a toothpick in an ureteral stone and a hairpin in a renal calculus.

The experimental production of reflux by slitting the submucosal ureter has its counterpart in man in ureteral meatotomy for stone and ureterocele, and in nonoblique re-

implantation of the traumatized ureter.

Common Causes of Reflux in Children

To simplify this presentation I am eliminating reflux due to prostatism, to neuro-

Fig. 2 — Urogram 12 years after a Boari operation, which substitutes a tube of vesical wall for the distal ureter.

Fig. 3 — The “straight through” compared to the normal terminal ureter.

genic vesical dysfunction, to tuberculosis, and to operations. Within these limitations the commonest cause in children appears to be a localized anomaly in which the ureter passes straight through the vesical wall (Figure 3). It may be unilateral or bilateral and may occur without any other anomaly. It has also been attributed to a “weak trigone,” to some abnormality of Waldeyer’s sheath (Figure 1) and, of course, to the thin-walled bladder of the megacystis syndrome. Reflux occurs both with and without obstruction to urination, which probably serves to aggravate rather than to cause the disorder, unless protracted and severe.

This applies also to valves of the posterior urethra and to such other obstructive lesions in the male as interfere only *mildly* with urination. However, the more severe and long standing lesions probably both initiate reflux by thinning the detrusor and aggravate its effects by increasing the voiding pressure.

One can only speculate on the role of infection in causing reflux in children; in most instances it is probably a complication rather than a cause, although Hutch and others have shown that it may accompany acute cystitis in the adult female, and disappear with its subsidence.

The Clinical Picture

The disorder most often manifests itself as recurrent or chronic urinary infection; reflux should also be considered in children with symptoms of obstruction to urination.

Fig. 4 — Slight dilatation of terminal ureters suggesting (but not proving) presence of reflux.

Continued

Renal pain during or after urination is uncommon. Markland has pointed out that reflux may remain asymptomatic until renal failure from hydronephrotic atrophy appears in later life.

Recognition

The excretory urogram may be normal but will often disclose some dilatation of the pelvic ureters (Figure 4). Ureteropyelectasis is always suggestive. It is feasible, but tedious, actually to demonstrate reflux in the urogram if stasis is not too severe. After a late film has shown the upper tract fairly empty, another is exposed after appearance of the desire to void, and a last one during micturition (Figure 5). Refilling and dilatation of the upper tract are diagnostic.

Cystourethrography

We ordinarily expose a large film after filling the bladder to the point of tolerance,

*The patient voids into a metal container with the microphone of a tape recorder attached. One thus gets information about the force of the stream, intermittency, and volume voided per second.

a second one during micturition, and a third one just afterward. I have learned not to lean too heavily upon the configuration of the urethra, since psychic inhibition may make it look small, and the internal meatus spastic, when both are actually normal. Conversely, one may find at operation a rigid internal meatus which looked normal in the urethrogram. Valves of the prostatic urethra are, of course, readily identified (Figure 6).

Cine

Cine cystourethrograms have the advantage of showing (sometimes) ureteral peristalsis as well as the behavior of the bladder and urethra — if well done. The longer period of observation increases the chances of observing fleeting reflux; but is such reflux important?

I believe that the "piddle pattern"* of Lyon and Smith is a better guide to the adequacy of the bladder and of its outlet than is either of the preceding methods, but one must put everything together.

Fig. 5 — Demonstration of reflux during excretory urography. (a-left) Twenty minute film; (b-right) Voiding film showing refilling and distention of upper tract.

Cystoscopy

At *cystoscopy* one calibrates the female urethra with olivary bougies with a view to correcting any distal narrowing; these bougies are too traumatic in the male. Visual observation is a poor guide to minor abnormalities around the internal meatus in the female, so much so that I wonder whether the "weak trigone," which Hutch regards as important in the production of reflux, may not also impede normal micturition. It is generally accepted that contraction of the trigone pulls open the internal urinary meatus; if this action is incomplete or defective, it seems likely that micturition will require an abnormally high pressure with a small stream. It requires alertness and experience to recognize those valves of the posterior urethra which are inframontane.

Absence of trabeculation suggests absence of outlet obstruction. False trabeculation can be produced by deliberate overdilatation of the bladder under anesthesia. One sees gaping ureteral orifices without demonstrable reflux and submucosal ureters of appar-

ently normal length with total reflux.

Hutch and others have observed that the trigone is likely to be wider than normal in the refluxing patient. Cystoscopic findings may be inconclusive or misleading; this examination should always be supplemented by cystourethrography if reflux is suspected.

Both Amar and Matzkin have demonstrated reflux cystoscopically by first distending the bladder with a solution of indigocarmine, draining it, and then watching the ureteral orifices. Blue spurts therefrom are diagnostic but are not an index of the severity of ureteral or renal damage.

A Simplified Clinical Classification

I. All may be unilateral or bilateral, and with or without ureteral duplication or obstruction to urination.

II. Fleeting

A. Incomplete

B. Total

III. Persistent complete

A. With normal upper urinary tract

B. With moderate dilatation

C. With severe dilatation and impaired renal function

Treatment

While opinions vary as to what should be done about reflux, it is agreed that any obstruction at the vesical outlet must be eliminated to minimize voiding pressures. Beyond that, views can be classified as follows:

Reflux

Never operate upon the ureters for reflux, but limit treatment to:

1. Training

a. Correct wiping

b. "Gentle" urination

c. Timed and double or triple voiding (What of untrained infants and of resistive teen-agers?)

2. Urethral dilatation, including avulsion of "distal urethral stenosis."

3. Meatotomy, urethrotomy

Plastic Operation

Always perform a plastic operation on the vesical neck with or without preliminaries. Both groups count on "maturation" of the

Continued

Fig. 6 — Reflux secondary to valves of posterior urethra. There is none into the upper segment on the right.

Fig. 7 — Reflux with intact upper urinary tract.

Fig. 8 — Reflux with definite dilatation of ureters and pelves.

bladder to thicken it and so to eliminate reflux (Hutch, Baker et al., King).

Vesicoureteroplasty

Always use vesicoureteroplasty, usually with a Y-V plasty or equivalent, if reflux can be demonstrated.

There is obviously room for the application of each of these methods. One should fit the treatment to the patient's problem rather than the reverse.

The Author's Views

For fleeting reflux, or for total reflux with little or no ureteral dilatation (Figure 7), correct any obstruction to urination, short of a plastic at the internal meatus; I believe that, if the bladder is to be opened, vesicoureteroplasty should be considered. Timed voiding and prolonged suitable antibacterial therapy are then instituted, together with close follow-up. If the mother is not intelligent, conscientious, and persistent, or if the child is too young to cooperate or is a rebellious teen-ager, this regimen will probably fail.

A conscientious follow-up is essential. It

Fig. 9 — A degree of hydronephrosis requiring preliminary nephrostomy.

includes periodic microscopic examination and cultures of clean voided urines, measurements of renal function for comparison, cystograms and urograms, bearing in mind the perils of over-irradiation.

If the conservative regimen fails, vesico-ureteroplasty, with or without Y-V plasty, should be considered.

If there is moderate dilatation with good renal function (Figure 8), treatment should be surgical, as just outlined.

If ureteropelvic dilatation is advanced

with definite impairment of renal function (Figure 9), preliminary nephrostomy is done; some will prefer cystostomy, which I dislike. If renal and ureteral function (cinefluoroscopy for the latter) improve, the ureters are narrowed, perhaps shortened and reimplanted, and the internal meatus is widened.

Should renal function fail to improve and the ureters remain inert, the next step is pyeloileoplasty, although there is a place, despite some impairment of peristalsis in

Fig. 10 — The Hutch operation.

Fig. 11 — Bischoff's method.

Continued

relatively thick walled ureters, for tubeless cutaneous ureterostomy with wide uretero-ureterostomy where the ureters pass through the abdominal wall. I have been disappointed with tubeless cystostomy.

Types of Vesicoureteroplasty

The Hutch Operation

First in point of time is the operation

of Hutch, designed originally to stop reflux in paraplegics (Figure 10). However, experience has shown that the principle of leaving a bare ureteral segment within the vesical lumen to be covered by mucosal proliferation is wrong, since scar often constricts the ureter as it enters the lumen of the bladder.

Fig. 12 — Technique of Politano and Leadbetter.

Fig. 13 — Paquin's operation.

Bischoff's Operation

The virtue of *Bischoff's* operation (1957 — Figure 11) is that it is unlikely to do any harm. However, it requires a considerable distance between ureteral orifices and internal meatus, and a large bladder; data concerning results are meager.

Politano and Leadbetter

The method of *Politano* and *Leadbetter* (1958 — Figure 12) has been most widely used and has yielded a high proportion of successes. It can be applied to any type of ureter. However, if dissection has to be carried high onto the ureter, there is some

Fig. 14 — Lich's method.

Fig. 15 — Mathisen's modification of the Politano-Leadbetter operation.

Continued

danger of injury to intraperitoneal structures so that, if one has to narrow or excise much of the ureter, it should be exposed extravesically.

Other Procedures

In 1959 *Paquin* (Figure 13) devised a method combining an ureteral cuff with oblique submucosal implantation; the operation is useable for any kind of ureter.

Lich's operation (1961) is made clear by Figure 14.

Mathisen's procedure (1964 — Figure 15) is essentially that of Politano and Leadbetter except that the ureter is buried in a trough instead of a tunnel.

The various techniques of ureteral advancement (Hutch, Williams, Witherington, Edelbrock), of which Figure 16 is an example, all require a reasonable distance from ureteral orifice to internal meatus.

Results of Treatment

It is difficult to assess these accurately from the literature. Some speak of the number of ureters, others of the number of patients; often the length of the follow-up is not mentioned. At other times it is hard to say whether the patients had only Y-V plasty of the vesical neck, or whether the

ureters were also reimplanted. In other instances reported series are too small for worthwhile evaluation. It is, for these reasons, often impractical to combine series in order to assess larger numbers.

Conservative Treatment

Stephens in 1962 reported on 34 patients observed for five to 10 years during and after protracted antibacterial therapy and "multiple micturition." Forty of 59 ureters (67.7 per cent) were still refluxing, a situation which he regards as of no importance as long as infection does not occur.

Leuzinger et al. in 1959 regarded 30 of 44 patients treated conservatively for an unstated period as "improved," a statement too vague for analysis. This left 32 per cent unimproved and presumably refluxing.

Melick and associates (1966) found, after a followup of one or more years of conservative therapy, that 56 per cent still had reflux.

King has stated that antibacterial therapy and multiple micturition will result in disappearance of reflux in three fourths of patients in whom the disorder is uncomplicated, i.e., no outlet obstruction, neurogenic dysfunction, etc. However, he has presented no specific data.

Fig. 16 — William's ureteral advancement.

Plastic Operations on the Vesical Neck

One can, for this purpose, combine the results of the various plastics with those of transurethral resection. The series of Pasquier et al., the Leadbetter, Melick et al., and Harper and Politano add up to 106 patients, of whom 60, or 56 per cent, still had reflux at an unstated time after operation.

Vesicoureteroplasty

The operation of Politano and Leadbetter has been most consistently successful. Politano followed 100 patients for five years; Scott reported on 66 ureters, and Williams on 57 patients: a total of 217 instances, with reflux persisting in eight or 3.7 per cent.

McGovern has summarized the results of the Paquin operation in 327 ureters in 226 patients followed for an average of 4.5 years. Reflux was still present in 10 per cent.

In the case of Mathisen's method, he saw reflux persist in 10 of 44 patients, while Bettex saw it in 18 of 101 ureters, a combined failure rate of 19 per cent.

In regard to Hutch's operation, only small series have been reported. Combining the series of Pasquier et al., Fuqua and associates, Johnston, Williams and Eckstein, and Ambrose and Nicholson, we find that reflux persisted in 24 of 121 patients, or 20 per cent. One must bear in mind Hutch's own statement that this operation is too often followed by stricture where the ureter enters the vesical lumen.

Causes of Failure

Since this presentation is not concerned with surgical technique, causes of failure of vesicoureteroplasty are merely summarized. They appear to result largely from errors of judgment and of technique. Included are reimplantation of ureters which are too large, or of those in which peristalsis is inadequate. Also operative are constriction at the site of reimplantation and unduly sharp angulation of the ureter.

Comments and Conclusions

The phenomenon of vesicoureteral reflux has been known and studied for at least 125 years, during which time it has become

firmly established as abnormal in mankind. During this period its causes (local anomalies, urinary infection, obstruction at the vesical outlet, neurogenic vesical dysfunction, thin-walled bladders, and operations upon the ureterovesical junction) have become well known. Its deleterious effects upon the urinary tract are also well understood and have ample experimental confirmation. However, deliberate attempts to correct it surgically date back only about 15 years, although plans to prevent it by oblique submucosal reimplantation of the injured ureter are much older.

The objective of treatment is to stop the noxious effects of reflux and to eliminate infection. While opinions differ sharply as to whether the definitive therapy should be medical or surgical, it is generally agreed that any vestige of obstruction to urination must be eliminated by whatever method required.

Beyond this, opinions are divided into two divergent groups: those who decry vesicoureteroplasty, and those who advocate it. The first group, maintaining that reflux per se is harmless, put their faith in a long time bacterial therapy and in timed, multiple micturition. A subgroup holds that the bladder may, as it matures, thicken and stop the reflux. Should this fail to occur, however, the patient will have to maintain constant vigilance throughout his life in order to protect his urinary tract. Experience with patients makes me doubt that many will do so over the long run, and there is acceptable evidence that many instances of terminal renal failure result from unrecognized, life-long reflux.

Since vesicoureteroplasty, particularly of the Politano-Leadbetter and Paquin types, has yielded good results in more than 90 per cent of suitable cases with a low incidence of complications, it seems sensible to say that, if a reasonable trial of closely supervised and conscientiously executed conservative therapy fails to eliminate the reflux, vesicoureteroplasty should be considered. There are, of course, situations in which the ureters gape, and total reflux

Continued

ADVANCES

occurs at low intravesical pressures and volumes, in which vesicoureteroplasty should receive first consideration. There are others

in which renal and ureteral damage is so far advanced that urinary diversion offers the only hope of halting renal destruction of the kidneys.

My First Consultation

My first medical consultation was a curious experience. In a severe case of pneumonia in an elderly lady I called in consultation a kind-hearted physician of high standing who had been present in Cincinnati at the time of my father's fatal illness. This gentleman, after seeing the patient, went with me into the parlour. There he began to walk about the room in some agitation, exclaiming, 'A most extraordinary case! Such a one never happened to me before; I really do not know what to do!' I listened in surprise and much perplexity, as it was a clear case of pneumonia and of no unusual degree of danger, until at last I discovered that his perplexity related to *me*, not to the patient, and to the propriety of consulting with a lady physician. I was both amused and relieved. I at once assured my old acquaintance that it need not be considered in the light of an ordinary consultation, if he were uneasy about it, but as a friendly talk. So, finally, he gave me his best advice; my patient rapidly got well, and happily I never afterward had any difficulty in obtaining a necessary consultation from members of the profession.*

Hearing Aid Referral

THE PRIMARY problem of hearing aid referrals seems to be one of a lack of information on — *what to do* — with the hard-of-hearing patients who cannot be helped by medical or surgical means. These patients are often left to the mercy of the hearing aid salesmen, with little more counselling than: "You need a hearing aid." After this meager recommendation the patient usually ends up with a high-priced hearing aid, which he often does not wear due to an inadequate fitting.

This problem of "blind" hearing-aid referrals has been reduced by the availability of professionally trained personnel in the larger Otolaryngology Practices and in University Speech and Hearing Clinics. At these facilities, specific recommendations for hearing aids are made by Audiologists who hold a Ph.D. or an M.A. Degree. Briefly, a patient receives initial counselling in regard to hearing aid wear, complete speech testing to assess the feasibility of hearing-aid wear, recommendation for a hearing aid, and a follow-up examination and counselling after the patient has been exposed to hearing-aid use.

Otologic and Audiologic Evaluation

Usually, a potential hearing-aid user has had an examination for his hearing problem prior to his purchase of a hearing aid. However, this is not always true and many hard-of-hearing patients have worn hearing aids for several years when an operation could have alleviated their problem.

Middle Ear Pathology

A good example of this is the patient with otosclerosis who has a good chance of gaining normal hearing after stapedectomy. A similar situation exists in cases with middle-ear effusion. A serous otitis media, unless treated early, can easily develop into a more complicated problem with ultimate loss of function of the complete sound-conducting mechanism (tympanic membrane and ossicular chain). From these two examples, it is obvious that a complete otologic and audiologic examination is mandatory for all potential hearing-aid wearers, especially those patients who are currently wearing hearing aids and have not had an examination.

Examination

After a complete examination has been made and all medical and surgical remedial means have been explored, the hard-of-hearing patient's problems begin. Where does he go? What kind of a hearing aid is best

Continued

for him? On which ear should he wear the aid? Should he have two hearing aids? Is his hearing loss great enough to warrant a hearing aid? All of these questions and more are common to the potential hearing-aid wearer and most of them can be handled in an initial counselling session with the patient. Specific recommendations can be made based on the audiologic examination which includes pure-tone threshold audiometry and speech testing. The pure-tone threshold examination gives a graphic representation of the patient's ability to hear sinusoidal pure tones at discrete frequencies in octaves from 125-8000 Hz. The speech testing gives important information in regard to the speech-reception threshold** and maximum speech discrimination score.**† The combined test scores give the examiner a realistic picture of how the patient can function in everyday speaking situations and also form an initial basis for the recommendation for or against hearing-aid wear.

Initial Counselling

The initial counselling session is based on the pure tone and speech testing described above. These tests give the examiner the amount and extent of hearing loss of the patient and thereby present a baseline for initial recommendation. In addition, the patient's attitude to hearing-aid use is explored in the initial counselling session, i.e.: is the patient completely negative or at least receptive to trial of a hearing aid. Questions such as those stated above are answered at this time (type of aid† — which ear — etc.) and of course differ for each hard-of-hearing patient. For example, the recommendations for different age groups (the young child versus the adult) would obviously be different, each having their own esoteric aspects.

Hearing Aid Recommendation

Following initial counselling, a hearing aid is recommended usually by one of two methods.

Method One

This method involves trying several different hearing aids on the patient, each of which is tested by speech in a soundproof room through a loud speaker. The hearing aid with the best speech score is then recommended for the patient.

Method Two

This method consists of recommending a hearing aid based on audiometric testing which is "custom-fitted" to the hearing loss. In this method the hearing aid is then worn on a trial basis for two or three days and the patient is tested in a sound field following his trial to give an objective score of his performance with and without the hearing aid. By using this method the patient has the added advantage of knowing how he

*The speech reception threshold is the sound pressure level at which the patient can repeat simple spondee words. The speech reception threshold is measured in decibels from the point at which the average normal ear speech reception threshold has been established. This point is called 0 speech reception threshold. Experimentation has established the average normal speech reception threshold to be about 18-20 decibels above the standard physical reference pressure of 0.0002 dyn/cm².

**The maximum discrimination score is measured by administering lists of so-called phonetically balanced words at levels well above the patient's speech-reception threshold. These lists contain 50 monosyllabic words, chosen scientifically in order that each list will contain samples of speech sounds in the same proportion in which they occur in everyday speech.

†Currently there are four basic types of hearing aids: (1) behind-the-ear models, (2) in-the-ear models, (3) eye-glass models, and (4) body-worn models.

would function in his everyday environment, in addition to objective measurements of his performance with and without his hearing aid. Further research will indicate which method will be generally adopted.^{1,2,3}

Follow-Up Counselling

Whatever method of recommendation is used, it is extremely important that the patient receive adequate follow-up counselling in regard to hearing-aid wear. Adjustment to the hearing aid is critical, and if the patient is not counselled in this regard, he may not wear the aid and thus not receive the benefit he should from adequate amplification. In addition, he suffers the monetary loss incurred from the purchase of an expensive prosthetic device that is not used. Counselling should also be left open-ended and not be a one-shot affair. The patient should feel free to come in and discuss any electro-mechanical problems that arise with his hearing aid or specific adjustment problems that become evident with continued use of the aid.

Summary

The problem of proper hearing aid referral is in providing information on the existence of facilities with professionally trained personnel where hearing-aid recommendations can be made. The potential hearing-aid user should receive a complete audiometric examination, initial counselling on hearing-aid use, recommendation for a specific hearing aid and follow-up testing and counselling. The benefits of such a program for the potential hearing-aid wearer, in contrast to "blind" hearing-aid referrals, are obvious.

Remedies Derived from the Lion

Lion's fat, mixed with oil of roses, protects the skin of the face from all kinds of spots, and preserves the whiteness of the complexion; it is remedial also for such parts of the body as have been frozen by snow, and for swellings in the joints. The gall, used as an ointment in combination with water, improves the eyesight, and, employed with the fat of the same animal, is a cure for epilepsy; but a slight taste only must be taken of it, and the patient must run immediately after swallowing it, in order to digest it. A lion's heart, used as food, is curative of quartan fevers, and the fat, taken with oil of roses, of quotidian fevers. — Pliny.

Business is business.

Says who?

Says too many people.

You've probably heard it yourself many times.
It's used to justify almost *anything*.

But how many times have you ever questioned this attitude or raised your voice in protest? An idea like this takes root just because not enough people do anything to stop it.

If you have ever asked yourself "Why doesn't someone do something about it?" you're talking to the right person. You.

It won't be easy. Sometimes you'll need encouragement. The kind you'll find in your place of worship.

Here you'll discover you're not alone. That, in itself, can give you the strength to say "Says who?" once in a while when it needs to be said.

Grand Rounds

*First Stage Coagulation Disorders**

OLE JERDE, M.D.
Medical Resident

NUMEROUS ADVANCES have been made in recent years regarding the knowledge of the coagulation mechanism. Certainly the improved laboratory procedures, various assays, standardization of technique, as well as better communication between researchers here and abroad have been major reasons for these advances. As discoveries of various factors were made in countries throughout the world, different terminology was used to identify these factors. In 1959 there were at least 64 synonyms for ten distinct clotting factors.¹ Standardization of the nomenclature is a great relief to the non-coagulationist.

The purpose of this paper will be to discuss the evaluation, diagnosis, and treatment of first-stage coagulation disorders.

Mechanism of Coagulation

The Figure from Kerr¹ depicts the coagulation scheme and is similar to that found in many textbooks. The factors exist in the inactive form in the circulation and are enzymatically activated during coagulation. MacFarlane² states that the Hageman factor (XII) is activated by coming in contact with surfaces and substances other than the vascular endothelium. The activated Factor XII enzymatically activates Factor XI which, in turn, leads to activation of Factor IX. This same process continues through the first five reactions and has been termed the "enzyme cascade" by this author.² Factor X can be activated both in the intrinsic as well as in the extrinsic system by contact with tissue factor and Factor VII.¹ Information about Factor V is incomplete, but this may be a proteolytic type of activation. Phospholipid is involved in the activation of Factor V, and probably in that of Factor VIII as well.² Calcium is also needed, but the exact site of action is not known. Variations in the serum calcium level

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, October 18, 1966.

Continued

do not alter the speed of reaction. Most of the actual time involved in coagulation occurs in the first stage.

Disorders of First Stage Coagulation

Deficiencies in the clotting factor can be divided into two groups: acquired and hereditary. As a general rule acquired coagulopathies may affect more than one factor while congenital disorders are of a single deficiency.³ However, with improvement in laboratory techniques, inherited deficiencies of more than one factor have been reported and will be discussed later. In adult medicine the most common acquired coagulopathies are due to anticoagulants and liver disease.³ Levels of Factors VII, IX, and X, in addition to prothrombin, are all decreased by the coumadin type of drugs. These have been termed the vitamin K-dependent factors,⁴ since vitamin K is essential for their synthesis in the liver. Severe liver disease can cause a deficiency of the above four factors. Factor V is produced in the liver and may be deficient in severe liver disease.³ While it is generally associated with disease states producing hypoprothrombinemia it is not dependent on vitamin K for production.

Factor XII deficiency was first discovered by Ratnoff and Colopy⁶ in 1953 in an asymptomatic man who was found to have a prolonged clotting time. He had had operations and dental extractions but had not had bleeding problems. Other reported cases revealed no or minimal clinical problems.⁷ A few cases have been reported in which ecchymoses and severe hemorrhage did occur.³

*Kerr, C. B., *Journal of Medical Genetics*, 2:256, 1965.

Figure

In the early 1950s it was found that hemophilia was not a single disease but rather three different disease entities which presented with very similar clinical pictures.^{8,9} These factors are easily separated by the use of serum and barium sulfate-treated plasma. Factor VIII deficiency (AHG) is corrected by barium sulfate-treated plasma but not by serum; Factor IX deficiency (PTC) is corrected by serum but not by barium sulfate-treated plasma, while Factor XI deficiency (PTA) is corrected by both.⁸

Factor VIII and IX deficiencies are sex-linked recessive inherited disorders while PTA deficiency is of autosomal inheritance.¹ Kerr¹ states that PTA deficiency is an incomplete recessive defect while Conrad et al.¹⁰ believe it to be a dominant autosomal disorder, affecting both sexes.

It was thought that while females were carriers and would pass the trait on to their offspring they themselves were not clinically affected. The belief was that this was a lethal condition for the fetus.¹¹ In recent years, however, several cases of homozygous hemophilia in females have been reported.¹¹ These authors reviewed the literature and presented a woman who had had bleeding difficulties since childhood. Judging from family analysis this patient was thought to be a heterozygote. Factor VIII levels were determined and found to be very low. This is a very rare occurrence, and it was postulated that a mutant gene may have been responsible.

Conrad et al.¹⁰ reviewed the literature regarding the relative incidence of these three deficiencies and found that AHG deficiency accounted for 64 to 86 percent, PTC deficiencies range from 11 to 18 percent, and PTA deficiencies, 1 to 18 percent of the total. Conrad reported 82 cases in his series and found that AHG deficiency accounted for 16 percent, PTC deficiency for 4 percent, and PTA deficiency for 80 percent. His series probably does not reflect a true cross section of the population since he investigated military personnel as well as their dependents, and states that people with overt AHG and PTC deficiencies were rarely seen. These authors feel that of these three disorders, PTA deficiency is more often benign and easily missed unless complete diagnostic studies are made. Of their 65 patients with PTA deficiency, 22 cases were asymptomatic, but were evaluated because of a family history of bleeding disorders. Most of the other patients had histories suggestive of a clotting defect, or presented with bleeding problems. The mild forms of these three disorders have been termed the "occult hemophilias."¹² These are patients who have few symptoms, but who may bleed following trauma or surgery; and many cases have been discovered at the operating table. Patients with Factor VIII and IX deficiencies have been separated into three groups depending on the severity of the clinical picture, as well as factor levels.¹ Severe hemophilia includes those with factor levels of 0 to 1 percent. The coagulation time is markedly prolonged and the patient will have had severe bleeding since early childhood. Spontaneous hemorrhages are common with hemarthrosis, hematomas, and hematuria, most of which will demonstrate permanent disabilities and should present no problems in diagnosis. In moderate hemophilia the factor levels range from 1 to 3 percent and the clotting time is only slightly prolonged. Bleeding does occur but is generally less frequent and less severe with fewer disabilities. In the third group are the mild or occult hemophiliacs with factor levels of

Continued

3 to 30 percent and a normal clotting time. These patients rarely have spontaneous hemorrhages and often live a normal life. The mechanism which controls the production of these factors is unknown,¹² but multiple alleles may be involved. This might explain the broad range of factor levels found in normal people as well as in bleeders.

Factor X deficiency (Stuart's disease) is a very rare bleeding disorder with only 20 proven cases reported in the literature.¹³ Clinically this disease is very similar to the previously described disorders with spontaneous hemorrhage and bleeding following trauma. Hemarthrosis occurs, and in the case presented the patient required transfusions for excess menstrual flow.¹³ Clotting time, prothrombin time, and the partial thromboplastin tests were abnormal. Specific assays revealed less than 1 percent concentrate of Factor X. This is an autosomal recessive inherited defect.^{1,13} The heterozygotes, while clinically normal, were easily distinguished on the basis of Factor X level.

Adequate Factor VII levels are required for normal hemostasis and it is thought that this factor functions only in the extrinsic system in the presence of tissue juice.¹⁴ While there is some disagreement about inheritance, most studies would indicate that this is an autosomal recessive trait, with equal sex predilection.^{1,15} While the carriers have decreased factor levels to 50 percent of normal, they do not have a bleeding tendency.¹⁵ Deficiencies of this factor cause clinical bleeding problems which are very similar to other first stage defects.¹⁵ While bleeding after dental extractions is quite severe, several patients have had major surgery without blood loss.^{16,17} Even though blood levels are low, there is a wide variation in the severity of clinical bleeding problems,¹⁷ and the mechanism here is not known. Of interest is that one of Hall's¹⁷ patients died from pulmonary emboli illustrating that this isolated defect does not protect against venous thrombosis. Vitamin K preparations, even in massive doses, are of no help in the congenital condition.¹⁶

Congenital Factor V deficiency (labile factor), while rather rare, has been reported from various areas in the world.¹⁸ This is an autosomal gene, probably recessive, with equal sex incidence.¹ The heterozygote, while having slightly prolonged prothrombin time, is not clinically affected. Clinically the bleeding is generally the capillary type with epistaxis, purpura, and easy bruising. Trauma, surgery, and dental extractions may be followed by severe hemorrhage; however, O'Brien¹⁹ reported a patient who had had several operations without bleeding, but had had hemorrhage after dental extractions. Specific assays showed very low levels of Factor V. Vitamin K does not alter the prothrombin time and has no beneficial effect clinically.

While very rare, patients having multiple deficiencies have been reported.^{20,21} Statistically, the incidence of a combined deficiency of both Factor VIII and IX would be one in ten million.²¹ These authors studied a family in which several members had PTA deficiency, AHG deficiency, or increased vascular fragility. One of the family members was thought to have all three deficiencies. Verstraete et al.²⁰ studied four different families with PTC deficiencies and found a decrease in Factor VII activity in all patients with the disease. It is thought that proconvertin (VII) is bound to an inhibitor while in the inactive form, and that activation occurs by removal of this inhibitor. From laboratory studies it appears

that Factor IX may have a role in the activation of Factor VII. These authors feel that in patients with PTC deficiencies there may be delayed activation of Factor VII rather than an actual deficiency. Inhibitors and circulating anticoagulants may be present and complicate the picture even more.²¹

Diagnosis of First Stage Defects

History

As with most medical problems a detailed, carefully taken history is the most important part of the evaluation,²² but, as noted previously, there are mild forms of these diseases in which there may be no history of bleeding tendencies. Another point is that the patient with mild bleeding tendencies may have learned to live with his disease and does not regard himself as a bleeder. A great deal of medical judgment is needed to evaluate whether a bruise is significant or what frequency of epistaxis is abnormal. Also the reliability of the patient must be considered, and at times a history may be misleading.²³ Specific questions must be asked regarding the frequency of epistaxis and the degree of bruisability.²² Questions must be asked about circumcision, dental extraction and other operations, hematomas following injections, trauma, hemorrhage from the genitourinary and gastrointestinal tract as well as hemarthrosis.²² Questioning must also include menstrual history. A detailed family history should be taken including an inheritance pattern, since over 90 percent of congenital bleeding disorders are either Factor VIII or IX deficiencies²² and are sex-linked. A negative family history, however, does not rule out bleeding problems, since 25 percent²² to 50 percent²³ of hemophiliacs will give a negative family history. A thorough physical examination with particular emphasis on the skin and joints must be done on all patients.

If the history is at all suggestive of a bleeding disorder a complete laboratory evaluation must be done.

Laboratory Studies

The whole blood coagulation time has been discontinued as a screening test for bleeders by several authors^{10,24,25} since it is often normal in mild forms. Diamond and Porter²⁵ reported on 19 patients with normal bleeding and clotting times; however, special tests proved that all 19 patients had either PTC or AHG deficiencies. They also reported nine cases with abnormal Lee-White tests, in which other special studies were normal. Since the test was of no help and often misleading, it should be discontinued for screening patients.²⁵

The partial thromboplastin time (PTT) test was originally described by Langdell, Wagner, and Brinkhouse in 1953,²⁶ and has proved to be a good screening test, which can be used to detect deficiencies of Factors XII, XI, X, IX, VIII, and V in addition to fibrinogen and prothrombin.²⁷ The PTT test is not sensitive to Factor VII deficiencies, but this can be evaluated by the one-stage prothrombin time. The PTT test will also be abnormal if an inhibitor is present.²⁷

The prothrombin time (one-stage) is sensitive to deficiencies of prothrombin Factor VII, V, X and fibrinogen²⁴ and is recommended for all possible bleeding problems.

Continued

The PTT test does not detect platelet abnormalities so that platelet count, bleeding time, tourniquet test, and clot retraction may be needed for complete evaluation.²⁴

Conrad et al.,¹⁰ in evaluating PTA deficiencies, found that the thromboplastin generation test was more accurate than the PTT or prothrombin consumption test, and recommended that the TGT be done on all possible bleeders.

The coagulation work-up as proposed by Krivit and White²⁴ using the PTT test, prothrombin time and platelet functions should detect most clinical problems. If these tests are borderline and the history suggestive of a bleeding disorder, further tests can be done.

Treatment

In the past, fresh blood, fresh plasma or fresh-frozen plasma has been used for the control of acute bleeding episodes in Factor VIII-deficient patients. Fresh plasma will generally control the bleeding in soft tissue injuries; however, it is difficult to maintain adequate Factor VIII levels to prevent hemorrhage during surgery or after dental extractions by the use of plasma alone.²⁸ It may take one liter of fresh plasma to raise the AHG concentrates to 15 percent in the severe hemophiliac,²⁹ and concentrations of 25 to 40 percent are required during surgery and following dental extractions to achieve adequate hemostasis.^{28,29} Since the life of AHG in the circulation is rather short, frequent infusions are necessary and may lead to congestive heart failure. The development of concentrates of AHG have made surgery a safer procedure for the hemophiliac.

McMillan et al.³⁰ report their experience with the use of the Fraction I of Cohn, which is a Factor VIII concentrate containing significant amounts of fibrinogen. Factor VIII is seven times as concentrated as in normal plasma, which considerably decreases the volume load. Their results were quite good except where therapy was stopped too soon. Oozing occurred but promptly ceased when more of the concentrate was given. Levels of fibrinogen up to 1,000 mg./100 ml. plasma were observed and two patients developed hemolysis, which stopped when the fibrinogen returned to normal levels. One case of hepatitis occurred, but this patient had also received blood and plasma.

In Britain both bovine and porcine concentrates are readily available and frequently used where large amounts are needed.³¹ Good control was obtained in their series; however, these are antigenic and can be given for only a limited period of time.

Pool and Shannon³² report on a method of producing a cryoprecipitated* AHG concentrate which can be done in the local blood bank. This is highly concentrated with 30 times the level of AHG compared to frozen plasma. High blood levels were easily maintained in the one case studied by giving the concentrate every 12 hours. No adverse reactions were noted.

Webster et al.³³ report on the use of a glycine precipitated concentrate. There is from three to eight times more AHG per gram of fibrinogen compared with the Cohn fraction. Large amounts were infused without any side effects. Following the initial infusion it had a half-life of eight hours, but after repeated infusions the half-life was 14 to 16 hours. Theoretically the difference is due to diffusion into the extracellular compartment.

Because of individual variation no simple dosage schedule can be de-

*See Test Your Word Score Page 687.

terminated.²⁸ Bleeding and infection will increase the amount needed. For the surgical patient Tornay suggests giving therapy every eight to 12 hours for 12 to 16 days following the operation. While specific assays for Factor VIII levels are the best guide for controlling the patient,²⁸ the PTT test is of help.³⁴

There are no concentrates available for treating PTC deficiencies; therefore fresh plasma or blood must be used.²⁹ Stored plasma may be used; however, fresh is preferred. The half-life of Factor IX ranges from 18 to 30 hours with an average of 24 hours.³¹ Barrett²⁹ recommends giving one unit of fresh plasma every six hours following a surgical procedure until healing has occurred.

The initial half-life of Factor XI is 60 to 80 hours, and after repeated infusion a delayed second half-life is observed of up to 190 hours.³⁵ Adequate hemostasis can be achieved with either stored or fresh plasma; however, fresh plasma gives longer results.⁵

Factor X has an infused half-life of about 48 hours.³¹ The active bleeder can be controlled by plasma or serum.⁵

Factor VII, while stable in vitro, is rather short-lived in the circulation with a half-life of five hours.¹⁶ In spite of this short half-life, plasma will stop the bleeding and prevent further hemorrhage for three to four days.¹⁵ One of Mauder's patients received 19 ml. plasma/kg., then had extensive dental work without bleeding and required no further therapy.

Factor V has a survival time of 24 to 48 hours.⁵ Bleeding problems can be controlled with fresh blood, fresh plasma, or fresh-frozen plasma.^{5,18}

Case Report

A 16-year-old white male was admitted to Hennepin County General Hospital on 8/28/66 because of a swollen, painful right knee. He had twisted this knee two days before and had had progressive symptoms.

Previous Admissions

1955 — Patient was admitted because of severe, persistent hemorrhage following tonsillectomy. The Lee-White was over one hour. Prothrombin time, clot retraction and tourniquet test were normal. He was treated with fresh-frozen plasma with good response. A diagnosis of PTC deficiency was made at the University of Minnesota.

1960 — Patient was admitted because of hemorrhage following a dental extraction. Bleeding stopped after one unit of blood.

1960 — Hemarthrosis, right knee.

1961 — Hemarthrosis, right knee.

1962 — Hemarthrosis, left knee.

1963 — Hemarthrosis, left elbow.

Family History:

An uncle and one nephew have bleeding tendencies. One nephew died at age three following skull fracture.

Physical Examination:

The physical examination was normal except for the swollen tender right knee. There was no warmth or redness present.

Laboratory Data:

PTT on 8/28/66 was 59. Control 46 Prothrombin time 15.2. Control 12.6.

Hospital Course:

The patient was treated with ice packs, rest and elevation. He received two units of fresh-frozen plasma on the day of admission and two units the following day. Convalescence was slow; however, the right knee was markedly improved and was without pain or swelling on discharge.

Venereal Disease A Serious National Problem, Says AMA

Venereal disease is spreading so rapidly that it now represents this nation's most urgent communicable disease problem.

VD is hitting particularly hard among teenagers and young adults, according to the American Medical Association.

The venereal diseases are infecting about two Americans a minute—3,000 a day, or 1,100,000 a year. Cases of infectious syphilis have almost tripled in this country in the past five years. More than a million

new cases of gonorrhea are developing annually.

VD can blind, cripple, and even kill.

The ravages of venereal diseases are all needless tragedy, says the AMA, because both syphilis and gonorrhea can be avoided. If contracted, they can be cured by prompt medical treatment.

The cure for both diseases—penicillin—has been available since 1943. Any family physician or public health clinic can administer

prompt treatment.

Venereal disease is caused by intimate personal contact.

Complacency, ignorance, and a free-and-easy attitude toward moral standards are partly responsible for the spread of VD; the increasing use of alcohol, especially among young people, also plays a role.

Authorities believe, however, that thousands of young people simply aren't aware of the dangers of VD. Once infected, they are complacent about treatment.

One of the first signs of syphilis may be a painless, ulcerating sore. Gonorrhea produces inflammation of the genital and urinary tracts, and a discharge of pus.

A person may contract syphilis and be unaware that he has the disease. After the first symptoms, the germs may remain hidden in the body for as long as 20 years before any damage is discovered. Then the person may become crippled, develop heart disease, blood vessel disease, blindness, or show mental symptoms. Even death may result from this hidden stage of syphilis.

If left untreated, gonorrhea may be responsible for arthritis, endocarditis, sterility, and blindness.

If a person suspects he may have contracted venereal disease, he should go to a physician immediately.

VD should be treated promptly by a physician.

Abstracts, Briefs and Commentaries

THALIDOMIDE AND CONGENITAL CLEFT DEFORMITIES

Among the suspected nongenetic factors in the etiology of cleft lip and palate in humans, the intake of various drugs in early pregnancy deserves attention. Aminopterin has been used to induce abortions. When abortion failed to occur, multiple congenital malformations in the child have occurred, among them cleft lip and palate. The typical embryopathy described in West Germany, Denmark, and other countries revealed multiple severe malformations. Nine women in Copenhagen requested abortion because they had used Thalidomide. Six had their pregnancy aborted. Three, because their requests were too late, completed pregnancy. One child was normal, one had bilateral aplasia, and the third had a cleft lip and palate. Since this publication three or four more similar deformities have been reported in Sweden and three or four in Japan.

The authors state that there has been a definite increase of cleft lip and palate. In Denmark this has been reported statistically (Frogh-Andersen 1963) : at present one in 500 newborn.

They suggest the possibility of such deformities resulting from other drugs during the early months of pregnancy. "This is not less probable when we consider the enormous abuse of tablets of nearly all kinds which has taken place during the last few decades, in most civilized countries: particularly sedatives, hypnotics, tranquilizers, and appetite-depressing drugs." Although Thalidomide is not available, a multiplicity of new drugs are on the market.

UMBILICAL VEIN ANGIOGRAPHY

A fascinating study of 60 cases of transumbilical catheterization of the portal vein are presented. Operative technique includes a small incision in the umbilicus through the linea alba. The umbilical vein remnant is found extraperitoneally. Amazingly, the lumen is merely collapsed but not adherent. A catheter is then advanced into the portal vein.

Continued

ABSTRACTS, BRIEFS AND COMMENTARIES

Pressure measurements can be made, and injection of radiopaque contrast material can outline the portal vein, the splenic vein and collaterals. There has been essentially no morbidity in 60 consecutive such catheterizations. This technique would be of particular benefit in cases where the spleen is not available for percutaneous puncture and study.

ECHINOCOCCOSIS OF THE LIVER AND LUNGS ANALYSIS OF NINETEEN CASES

These authors present 19 cases of echinococcosis cyst of the liver and lungs. The remarkable facet of this report is that 18 of the cases were contracted within the state of Utah. The life cycle of the echinococcosis is reviewed. The treatment recommended was complete excision of the cyst, whether in liver or lung, whenever possible. Marsupialization of the cyst is also recommended in cases where excision is impossible. A review of chemical sterilization of the interior of the cysts concludes that hydrogen peroxide and iodine are the most effective drugs. The increasing incidence of hydatidosis should be of great concern to both physicians and public health officials.

OSTEOPOROSIS

The decrease in bone mass observed in osteoporosis results from an imbalance between bone formation and bone resorption and may arise from (1) reduction in bone formation while bone resorption remains unchanged, (2) normal bone formation associated with increased bone resorption, (3) decrease in bone formation in addition to increased bone resorption, (4) an increase in bone formation with a greater increase in bone resorption, and (5) a reduction in bone formation greater than a decrease in bone resorption. Recent studies suggested that bone formation is normal or slightly increased in postmenopausal or senile osteoporosis, and that, instead, bone resorption is increased. Dietary studies in England and the United States indicate that patients with osteoporosis ingest less calcium in their diets than do their nonosteoporotic contemporaries. The osteoporosis seen in hypercortisonism seems due mainly to a decrease in bone formation. In the osteoporosis accompanying hyperthyroidism, increased bone resorption is the important factor in pathogenesis. On the other hand, in such conditions as osteoporosis of disuse, the decrease of bone mass is due primarily to a reduction in new bone formation. Relief of pain and improved retention of calcium have been demonstrated after therapy with anabolic hormones.

Book Reviews

If the truth be not diffused, error will be; if God and his word are not known and received, the devil and his works will gain the ascendancy; if the evangelical volume does not reach every hamlet, the pages of a corrupt and licentious literature will; if the power of the gospel is not felt through the length and breadth of the land, anarchy and misrule, degradation and misery, corruption and darkness, will reign without mitigation or end. — Daniel Webster

APPRAISAL OF CURRENT CONCEPTS IN ANESTHESIOLOGY, Vol. 3 — 1966. Edited by John Adriani, M. D. C. V. Mosby Co., St. Louis, Mo.

This third volume in the series bearing the same title again results from the program initiated at Charity Hospital in New Orleans in the teaching of anesthesiology. Trainees, and occasionally staff personnel, prepare papers on subjects of importance to those concentrating in this field, and these papers are then reproduced for distribution to all the department members. Dr. Adriani has edited a number of these reviews which are of the greatest interest and/or importance, and has compiled them in this book, thereby making this valuable information available to many others than just his staff.

The papers in this newest volume cover a variety of topics, such as pulmonary function tests, irreversible shock, use of pacemakers and cardiac monitoring equipment, drugs in cardio-respiratory resuscitation, and a worthy three-part review on the absorption, distribution, and elimination of volatile anesthetic agents. The book concludes with monographs for teachers in the field, suggesting how to instruct trainees and what they should know, and for the trainees it gives helpful pointers on how to prepare for and take written examinations. The basic concept of these papers is to review the early thinking and fundamental facts on a subject and then to expand this knowledge with a succinct review of the recent literature on that subject. Thus, all the papers represent the midpoint in thinking and knowledge in their area, for they are more current than the latest texts in the field and only slightly less current than the newest literature.

This latest edition of **CURRENT CONCEPTS** is better than its predecessors, for it includes topics of greater and, in many instances, more practical interest to the practitioner, and the approach in writing tends to favor the clinical more than the academic. The

book could be of interest to many others besides just those practising or teaching anesthesiology.

Richard O. Burmeister, M.D.
Midway Hospital
St. Paul, Minn.

PRIMER OF PERIPHERAL VASCULAR DISEASE — Travis Winsor, M.D. and Chester Hyman, Ph.D. Lea & Febiger, Philadelphia, 1965.

This monograph on peripheral vascular disease is well organized and adequately documented.

The chapter dealing with methods of study includes a number of items which deserve particular attention for the physician who is interested in making a thorough study of peripheral vascular abnormalities.

A bibliography is attached at the end of each chapter and the indexing is adequate.

The book is well bound.

Carl O. Rice, M.D.
Minneapolis, Minnesota

QUESTIONS AND ANSWERS IN ORTHOPAEDICS — Goodman and Schoedinger, III, Publication Date 8/66, Price \$9.85, C. V. Mosby.

This "book" consists of 213 pages of multiple choice, single answer, multiple choice-multiple answer, and true-false questions on orthopaedics. The questions provide an excellent detailed general review of the field. The answers are in the back of the book and references with page numbers are given for each question.

The authors are currently residents at Barnes Hospital-Washington University. The book is written specifically for students, interns, residents, and board aspirants. Much effort has gone into compiling and formulating these questions and this fine effort should be rewarded by a wide circulation.

Harrison H. Farley, M.D.
Minneapolis, Minnesota

Should You Lease Equipment?

As is the case with many questions of an economic nature, there is no standard "yes" or "no" answer to this question of leasing versus owning equipment. Each such question must be analyzed in terms of the specific terms and conditions.

Leasing of equipment has developed over the past few years primarily out of a need for working capital by business and industry requiring abnormally large financial outlays for plant and equipment. Frequently these concerns can use their limited capital to better advantage in phases of their business other than committing it semi-permanently to equipment.

In general, however, leasing companies are organized for profit. Certain volume purchase economies may be realized by the leasing companies, but in the final analysis, the lease payments must not only cover the cost of the equipment, but also financing and administrative costs — and a reasonable to excessive profit to the leasing company.

Many leasing companies use "tax savings" as a sales incentive. This is more imaginary than real, since the entire cost of purchased equipment may be recovered through regular or accelerated depreciation, just the same as the entire rental payment may be deducted. Usually, greater deductions through leasing result from the simple fact that the cost is greater.

For the individual interested (often ill-advisedly) in maximum possible tax deductions, such things as accelerated depreciation, 20% first-year depreciation and the 7% investment credit make it possible to recover as much as 75% of the cost of an asset in the first five years of its ownership. Frequently in the case of new practices, new partnerships or generally rising income, it will be advantageous to spread the deductions for recovery of cost on an asset over the longest possible period — a situation which does not lend itself to leasing.

In evaluating the specific merits of a leasing proposal, there are two primary considerations which must be scrutinized very carefully. First, what is the total cost of the asset to me if I lease and if I buy the asset? Second, what is the tax status of the payments I make?

A lease agreement which we evaluated recently clearly illustrates both of these factors. The lease was for five years and provided for rental payment of \$110 monthly. At the end of the five-year period, the Doctor could exercise an option to purchase the X-ray machine for \$300. An outright purchase of the machine would cost \$5,000.

Over the five-year lease period, this Doctor would pay \$6,600 in rental payments and then a final option payment of \$300 — a total of \$6,900. A cash purchase would require \$5,000, or \$1,900 lease. Even assuming a five-year credit purchase at 6%, the total principal and interest payment would be \$96.67 per month or a total of \$5,800. In other words, the Doctor is paying a premium of \$1,900 to lease if he has adequate funds available — or a premium of \$1,100 if he has to finance 100% of the purchase over five years.

Reduced to monthly terms, it would be over \$13 per month cheaper to buy than to lease.

Evaluation of the tax status of this particular contract is even more disappointing. The Internal Revenue Service screens these leases very carefully and requires that they have more aspects of a lease than a purchase agreement. A very important factor in this screening is the option price. If it is representative of fair market value at the option date, the arrangement will probably stand up as a lease. However, investigation of this particular contract disclosed that the value of a five-year old X-ray machine of this type could be estimated at \$2,400 to \$3,000. Comparison of this value with the \$300 option price indicates clearly that the option price is nominal.

In this case, after agreeing to pay an unreasonable rental price, the Doctor was faced with the probability of the Revenue Service classifying the transaction as a "Conditional Sales Contract" and therefore, requiring that the cost be amortized through depreciation over a ten-year life.

From a depreciation standpoint, the Doctor could take the 20% first-year depreciation of \$1,000 plus \$800 ten-year accelerated depreciation. In the second, third, fourth and fifth years, he could take an additional \$1,890 depreciation for a total of \$3,690. He could also take the \$800 interest paid over the five-year period.

Finally, he would be entitled to \$350 Investment Tax Credit — equal to a \$700 deduction in his 50% tax bracket. His total deductions would be equivalent to \$5,190 of the \$5,800 cash outlay over the first five years or 89½%.

On the lease he would pay out \$6,900 which would entitle him to \$5,090 depreciation. The \$483 Investment Tax Credit would be equal to a \$966 depreciation deduction increasing total deductions for the five-year period to \$6,056, or 87½% of the total outlay.

Obviously, this Doctor was not anxious to pay a premium of \$1,100 for a machine and then be able to deduct 2% less of that cost over the first five years.

While this is not a standard lease, it is quite typical of equipment leases from an economic standpoint. It can be generally stated that it takes a special set of financial circumstances to justify leasing instead of purchasing equipment for a Dental or Medical practice.

Only through careful evaluation of your specific circumstances and examination of the proposed lease can a determination of the validity of a leasing proposal be made. Obviously, the time for this evaluation is prior to the execution of the lease agreement.

The question of auto leasing has been dealt with in previous articles. In general, it has been concluded that unless you drive at least 25,000 miles per year — or are willing to pay a premium for the prestige of a new car each year and freedom from "ownership worries" — ownership of autos is also less costly than leasing.

114th Annual Meeting

Annual Meeting Program Set

A wide range of events including scientific sessions, round table luncheons, technical and scientific exhibits, banquets, a golf tournament, and business sessions await physicians attending the 114th Annual Meeting of the Minnesota State Medical Association May 15, 16 and 17 in Duluth.

All of the business and scientific sessions and the exhibits will be housed in the new \$6.1 million Duluth Civic Auditorium. The House of Delegates will convene Sunday, May 14, at 2:00 P.M. in the Auditorium, and on Tuesday, May 16, at 9:00 A.M.

The new members, county officers and delegates dinner is scheduled for Sunday evening at 6:00 P.M. in Hotel Duluth. Reference committees for the House of Delegates will meet Sunday at 8:00 P.M. Committee breakfasts will be held Monday, Tuesday and Wednesday mornings at 7:30 A.M.

Golfers will meet at 10:00 A.M. Sunday, May 14, at the Northland Country Club for the annual tournament. Bridge fans will want to attend the tournament scheduled for Monday night at 8:00 P.M. at the Duluth Hotel.

The Wednesday program will be devoted to discussion of current socio-economic topics of interest to all physicians.

All physicians are respectfully urged by the Committee on Scientific Assembly to visit the scientific and technical exhibits, and to express their appreciation to the technical exhibitors who have helped to make the meeting possible.

Dialysis or Transplantation — Yes or No

Is lifesaving renal therapy too costly? Is it fair to offer the patient doomed to die from renal failure the choice of dialysis or transplantation, knowing that neither choice is available to the average patient in need

of such treatment? What are the ethical, legal and philosophical aspects involved in sustaining the life of a doomed patient by use of dialysis or transplantation?

A panel representing the legal, medical and religious aspects of this problem will present their respective views at the Medicine and Religion Scientific Session scheduled for Monday, May 15, at 2:00 P.M. Members of the panel titled "M.D., L.L.B. and D.D. — Whither Goest Thou?" are the Rev. Dr. Paul B. McCleave, Department of Medicine and Religion, American Medical Association; Thomas E. Starzl, M.D., Associate Professor of Surgery, University of Colorado Medical School, and Mr. Burr B. Markham, member of the firm of Meagher, Geer, Markham and Anderson, Attorneys at Law, Minneapolis. Eugene Scott, M.D., Chairman of the Committee on Medicine and Religion, St. Paul, will moderate the panel.

Fertility and Sterility

Alan F. Guttmacher, M.D., New York, President, Planned Parenthood Federation of America, Inc., will discuss methods of birth control at the Scientific Session, Tuesday, May 16, at 4:00 P.M. devoted to the topic "Fertility and Sterility." Doctor Guttmacher is now considered by a number of observers as having inherited Margaret Sanger's role as prime mover of birth control. Discussing "Induction of Ovulation in the Treatment of Infertility" at the same session will be William N. Spellacy, M.D., Minneapolis, Assistant Professor, Department of Obstetrics and Gynecology, University of Minnesota Medical School.

Convulsive Disorders

Two Minnesota physicians will discuss "Convulsive Disorders" at the 2:00 P.M.

Continued

session on Tuesday afternoon. The participants are A. B. Baker, M.D., Minneapolis, Director, Department of Neurology, University of Minnesota Medical School, Minneapolis, and William R. Heilig, M.D., St. Paul, specialist in Neuro-Pediatrics.

Erythroblastosis Fetalis

The 10:30 A.M. session on Tuesday will be devoted to the subject of "Erythroblastosis Fetalis" and will climax a six-week home study course in which approximately 100 Minnesota physicians were enrolled. Participants in the Erythroblastosis session are John M. Bowman, M.D., Assistant Professor of Pediatrics, University of Manitoba, and Rhinehart F. Friesen, M.D., a lecturer in Obstetrics and Gynecology at the University of Manitoba, and also a lecturer in these same subjects at the School of Rehabilitation. Attendance at this session is not limited to registrants for the course.

Cardiac Emergencies

Medical emergencies under the title "Doctor Blue — Where Are You?" will be discussed at the opening Scientific Session on Monday, May 15, at 9:00 A.M. The following physicians will discuss various aspects of cardiac emergencies: Harold Katkov, M.D., Wayzata; Carlos E. Harrison, Jr., M.D., Rochester; and Stephen M. Ayres, New York.

Iatrogenic Medical Problems — Dangerous Drugs

The 9:00 A.M. session Tuesday has the title "Iatrogenic Medical Problems — Dangerous Drugs." Participants include Raymond N. Bieter, M.D., Professor of Pharmacology, University of Minnesota, and Edward A. Carr, Jr., M.D., Department of Pharmacology, University of Michigan Medical School.

Here's How To Do It

Minnesota physicians will participate in a series of eleven five-minute "How To Do It" talks on Monday at 3:30 P.M. Physicians and their topics are as follows:—

Warts Cooking?

E. T. Ceder, M.D., Minneapolis

Constipation — Can't or Won't

Felix A. McParland, Jr., M.D., Minneapolis

The Plugged Catheter

B. J. McGroarty, M.D. St. Paul

Bloody Nose

O. E. Hallberg, M.D., Rochester

Threatened Abortion

Carl E. Johnson, M.D., Rochester

Painful Feet

Kenath H. Sponsel, M.D., Minneapolis

Contact Lenses

Theodore R. Fritsche, M.D., New Ulm

The Buzzing Ear

Barclay M. Cram, M.D., St. Paul

The Discharging Nipple

David P. Anderson, Jr., M.D., Austin

How to Inject a Painful Shoulder

Charles G. Sheppard, M.D., St. Peter

The Varicose Ulcer

Eric P. Lofgren, M.D., Rochester

Round Table Luncheons

Round Table Luncheons and physician participants scheduled for Monday at 12:15 P.M. include the following:—

The Hearing Aid Problem

Joseph H. Leek, M.D., Duluth — Leader; Craig Linnell, Ph.D., Audiologist, St. Paul.

Dialysis in the Community Hospital and the Home

J. C. Hunt, M.D., Rochester — Leader; Donald A. Duncan, M.D., Minneapolis; Fred L. Shapiro, M.D., Minneapolis; W. J. Johnson, M.D., Rochester, and Mr. Harris W. Feldick, Osage, Iowa.

Cancer Chemotherapy

B. J. Kennedy, M.D., Minneapolis — Leader; Harry F. Bisel, M.D., Rochester; and John H. Brown, M.D., Minneapolis.

Ongoing Coronary Disease

Carlos E. Harrison, Jr., M.D., Rochester — Leader; Stephen M. Ayres, M.D., New York; Wilbert J. Henke, M.D., St. Paul, and Harold Katkov, M.D., Minneapolis.

DULUTH

Field Diagnosis in Athletic Injuries

Edward D. Henderson, M.D., Rochester — Leader; E. D. Nelson, M.D., Minneapolis, and W. E. Proffitt, M.D., Minneapolis.

Annual Physical — Why?

A. Cabot Wohlrabe, M.D., Minneapolis — Leader; Karl W. Anderson, M.D., Minneapolis

The Neuter Sex

Valentine O'Malley, M.D., St. Paul — Leader, and others.

Round Table Luncheons and physician participants scheduled for Tuesday at 12:15 P.M. include the following: —

Medical and Surgical Treatment of Persistent Peptic Ulcers

Owen H. Wangenstein, M.D., Minneapolis, and James C. Cain, M.D., Rochester.

Drug Incompatibilities

Raymond N. Bieter, M.D., Minneapolis — Leader; Edward A. Carr, Jr., M.D., Ann Arbor, Michigan.

Erythroblastosis Fetalis

Peter Bartzen, M.D., Duluth — Moderator; Donald Larson, M.D., Duluth; Arthur Aufderheide, M.D., Duluth; Glen E. Holt, M.D., Duluth; John M. Bowman, M.D., Winnipeg, and R. F. Friesen, M.D., Winnipeg.

Diagnosis of the Unconscious Patient

A. B. Baker, M.D., Minneapolis.

The Thrombosed Hemorrhoid

William C. Bernstein, M.D., St. Paul — Leader; R. J. Spencer, M.D., Rochester, and John V. Thomas, M.D., Duluth.

Multiple Pregnancy

Alan F. Guttmacher, M.D., New York.

Duluth — May 15, 16, and 17

P·B·SAL·C

NON-HORMONAL ANTI-ARTHRITIC

Helps keep arthritic patients active

P-B-SAL-C is a dependable, effective salicylate formula for relief of pain due to rheumatoid arthritis, bursitis and fibrositis.

Its formula consists of a combination of sodium salicylate, para-aminobenzoic acid and ascorbic acid. This special combination provides higher, longer-lasting analgesic levels compared with salicylates alone. Each P-B-SAL-C Tablet is enteric coated to delay disintegration until it reaches the small intestine.

P-B-SAL-C, low in cost to your arthritic patients, will help keep them active.

Mail coupon for literature and samples.

FORMULA

Each enteric-coated P-B-SAL-C Tablet contains sodium salicylate 0.3 Gm., para-aminobenzoic acid 0.3 Gm., ascorbic acid 50.0 mg.

CONTRAINDICATIONS

Renal damage, salicylate sensitivity or in conjunction with sulfonamide therapy.

DOSAGE

Take 2 tablets four or more times daily.

ULMER

THE ULMER PHARMACAL CO.

1400 Harmon Place, Minneapolis, Minn. 55403

In Memoriam

Death has nothing terrible which life has not made so. A faithful Christian life in this world is the best preparation for the next. — Tyron Edwards

ROBERT L. BOWEN, M.D.

Dr. Robert L. Bowen, 79, prominent Hibbing physician and surgeon and active civic leader, died February 26. He was the founder of Hibbing's Mesaba Clinic and participated in the organization of the former Rood Hospital in Hibbing. Born in Oshkosh, Wisconsin, Dr. Bowen had practiced in Hibbing since 1919. He was graduated from the University of Wisconsin and completed his medical education at Rush Medical College in Chicago.

He was a former member of the Hibbing Board of Education, a fellow of the American College of Surgeons, a member of the American Medical Association and Range Medical Society, and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his wife and a son, Dr. Robert L. Bowen, Jr. of Eugene, Oregon.

KATHERINE A. NYE, M.D.

Dr. Katherine A. Nye, 80, life-time St. Paul family physician, died March 2. Born in Zumbrota, Dr. Nye received her medical degree from the University of Minnesota in 1914, the only woman in her class.

She has been the recipient of many honors including the University of Minnesota's outstanding achievement award. She held a life membership in the American Academy of General Practice, the first person to be so honored. For many years she was director of the St. Paul Bureau of Health Immunization Clinic and its part time medical ex-

aminer. Dr. Nye was also a former medical examiner for girls for the Ramsey County Juvenile Court, a physician for Welcome Hall Day Nursery and a staff member of the Amherst H. Wilder Foundation Dispensary. She was an honorary staff member of Miller, St. Luke's and Bethesda Hospitals and was cited by the Greater United Fund and Council, Inc. for outstanding service "in planning for human needs."

Dr. Nye was a member of the Ramsey County Medical Society and American Medical Association and a Life Member and 50 Club Member of the Minnesota State Medical Association.

She is survived by her sister, Dr. Lillian Nye of St. Paul, and a brother.

ELWYN R. BRAY, M.D.

Dr. Elwyn R. Bray, 88, retired St. Paul physician and surgeon, died March 19. He was born in Young America and lived in St. Paul fifty years. He retired from active practice in 1964.

Graduating from the University of Minnesota Medical School in 1901, he trained in eye specialization in London and Vienna. He was a member of the Ramsey County Medical Society, the American College of Surgeons, the American Academy of Ophthalmology and Otolaryngology, the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife, two daughters, and three sons, one of whom is Dr. William N. Bray of St. Paul.

THE S.S. HOPE is a floating medical center — a fully staffed and fully equipped modern hospital which is the vehicle by which Project HOPE fulfills its mission of carrying American medical treatment and training to foreign lands where such help is not only needed but wanted. Project HOPE is a nongovernmental, nonprofit organization which is financed solely by voluntary contributions from individuals and private enterprise of North America.

THEIR HOPE — Although thousands of natives are treated on ship and ashore, the primary objective of HOPE is teaching. Every HOPE physician, nurse, or technician has his local counterpart who is trained to continue modern treatment after the ship leaves. It is a seeding process which multiplies in the underdeveloped country to improve the health of its citizens and thus their productivity and thereby creates a progressive economy and a higher living standard. The kind of economy in which communism cannot thrive!

OUR HOPE — HOPE — an acronym for Health Opportunities for People Everywhere — is a young Project only in its fourth year of operation but already the evidence is incontestable that its missions are highly successful, not only in the interchange of medical knowledge but also in promoting international friendship and goodwill.

YOUR HOPE — HOPE's basic professional staff of nurses, technicians, etc., are paid a nominal salary but most of its teaching physicians and dentists serve without financial compensation. This makes it not only our most successful foreign aid program but also our cheapest. Nevertheless, private contributions are essential. You may participate by drawing and mailing a check to:

Project HOPE

P. O. Box 550 Chicago, Ill. 60690

VALIUM® (diazepam)Roche®

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Infants, patients with history of convulsive disorders, glaucoma or known hypersensitivity to drug.

Warning: Not of value in the treatment of psychotic patients, and should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly or debilitated patients (not more than 1 mg, one or two times daily initially) to preclude ataxia or oversedation, increasing gradually as needed or tolerated. As is true of all CNS-acting drugs, until correct maintenance dosage is established, advise patients against possibly hazardous procedures requiring complete mental alertness or physical coordination. Driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended. If such combination therapy is used, carefully consider individual pharmacologic effects—particularly with known compounds which may potentiate action of Valium (diazepam), such as phenothiazines, barbiturates, MAO inhibitors and other antidepressants. Advise patients against simultaneous ingestion of alcohol or other CNS depressants. Safe use in pregnancy not established. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Observe usual precautions in impaired renal or hepatic function. Periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side Effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances, acute hyperexcited states, hallucinations); changes in EEG patterns during and after drug treatment. Abrupt cessation after prolonged overdosage may produce withdrawal symptoms (convulsions, tremor, abdominal and muscle cramps, vomiting, sweating) similar to those seen with barbiturates, meprobamate and chlordiazepoxide HCl.

Dosage—Adults: Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 to 10 mg t.i.d. or q.i.d. *Geriatric patients:* 1 or 2 mg/day initially, increase gradually as needed and tolerated. (See Precautions)

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 50 and 500.

Roche Laboratories
Division of
Hoffmann-LaRoche Inc.

IMPORTANT NEW INSIGHTS INTO HUMAN RESPONSE TO EMOTIONAL STRESS:

Impressive new confirmation of the effectiveness of Valium®(diazepam)

Ask your Roche representative to arrange a presentation of this important and fascinating new technique of research in emotional stress in a new methodology...quantitative, objective measurement with double-blind controls.

special formula for a special problem

*specifically formulated
for symptomatic
relief of sinus headache*

Sinus headache is not a single entity,
but a chain reaction of pain.
It is facial pain—deep, dull, aching and
nonpulsating. It is referred pain—
originating in the nose and sinuses but
felt at another site. It may become
generalized pain and tension in head and
neck. It is one or all of these.

The Sinutab formula is designed
for symptomatic relief of sinus headache.

It provides two analgesics to relieve
pain and discomfort...an effective oral
decongestant to reduce mucosal congestion...
and an antihistamine to help
control allergic manifestations.

Side Effects: Epigastric distress, drowsi-
ness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive
or operate machinery if drowsiness occurs.

Use with caution in patients with thyroid
disease, heart disease, hypertension, diabetes
or kidney disease. Excessive dosage or
prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

WARNER-CHILCOTT
Morris Plains, N.J.

SINUTAB[®]

for sinus headache

Each tablet contains
150 mg. acetaminophen,
150 mg. phenacetin,

LOCUM TENENS: Want Minnesota licensed G.P. to take over practice for June, July, August. Living accommodations, excellent salary. Write: MINNESOTA MEDICINE — 376; 496 Lowry Medical Arts Building, St. Paul 55102.

Take five...

LABSTIX® provides 5 important urinary findings*—on a single reagent strip! That's *more* information than you can get from any other single reagent strip. You know the results in just 30 seconds—while the patient is still in your office—and readings are reliable and reproducible. LABSTIX is easy to handle, too. Never goes limp, even when wet, because it's made with clear, firm plastic. And results with LABSTIX are easy to read—color contrast between the test areas and the transparent plastic is clearly defined. An unexpected "positive" from testing with LABSTIX may help in detecting hidden pathology before marked symptoms are manifest.

*Blood; ketones; glucose; protein, and pH.

...Plus one

You can extend your testing scope by including ICTOTEST® Reagent Tablets, the 30-second determination for bilirubinuria—which can be an early sign of obstruction of the common bile duct, infectious hepatitis, or other liver disease. This test is also useful for detecting liver damage from carbon tetrachloride and other halogenated hydrocarbons used as industrial and household solvents. Positive findings with the urine-testing team of LABSTIX and ICTOTEST can represent significant guides to patient management in many clinical situations. "Negatives" may help rule out suspected abnormalities over a broad clinical range and are important for the patient's record.

S. Department of Health, Education and Welfare, Bureau of Medical Services, Division of Indian Health.

Minnesota Medicine at a Glance

Erythrocyte Sedimentation Rate — Spellacy et al

Page 645

Two commonly used oral contraceptive drugs, one of the combined and the other of the sequential type, are shown in controlled studies to have an elevating effect on the erythrocyte sedimentation rate. The mechanism responsible for this elevation is probably similar to that in pregnancy. Clinicians are cautioned to consider this effect in the interpretation of the erythrocyte sedimentation rate result in women who are taking oral contraceptive drugs.

The Disturbed Patient? — Babb and Steinhilber

Page 649

This is a pertinent discussion of difficulties in patient-physician relationships. Distressing aspects of behavior in two patients are described and evaluated in light of the adverse effect upon the clinical course that is provided by pejorative labeling and hostile attitudes promoted by the physician in charge and supported by ancillary medical personnel. Remedial effects of a more open, honest, direct attitude affording improved communication and transactions are described. Attention to the concept of this paper will lead to increased patient comfort and response to therapy as well as to increased physician (and other medical personnel) comfort and effectiveness.

Fluorescence — Peterson

Page 663

Fluorescence techniques are receiving wide attention in the diagnosis of diseases associated with altered immune mechanisms. The author briefly reviews the basic principles and techniques involved in studying tissue fluorescence. The use of acridine orange and tetracycline fluorescence in the diagnosis of malignant tumors is discussed. The complexity of the methods and the questionable specificity of the results are the main problems in the application of these techniques in clinical situations. However, the clinician should have some familiarity with the methodology, since with further study and development, fluorescent antibody tests may become important means for diagnosis of a large variety of diseases.

Dr. L. K. Onsgard of Houston, Minnesota, mailed a television set to his son in the service for his birthday. The Postmaster told him that for fifty cents more they would give it "Special Handling." To this the Doctor agreed and stated, "The next time you need a shot, for fifty cents more I will use a sharp needle."

some allergens are green

whatever their color,
shape, or size...

Benadryl[®]

(diphenhydramine hydrochloride)

PARKE-DAVIS

for control of
allergic symptoms

Whether the allergen is greenish or garish, unseen or unknown, your patient can get symptomatic relief with BENADRYL—the potent antihistamine with antispasmodic action. **INDICATIONS:** Antihistaminic, antispasmodic, antitussive, and antiemetic therapy. **PRECAUTIONS:** Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers if used with diphenhydramine hydrochloride should be prescribed with caution because of possible additive effect. Diphenhydramine

The pink capsule with the white band is a trademark of Parke, Davis & Company.

has an atropine-like action which should be considered when prescribing diphenhydramine hydrochloride. **ADVERSE REACTIONS:** Side effects are generally mild and may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, blurring of vision, vertigo, headache, muscular aching, thickening of bronchial secretions, restlessness, and insomnia have been reported. Allergic reactions may occur.

BENADRYL is available in Kapseals[®] of 50 mg. and Capsules of 25 mg.

00867

PARKE-DAVIS

Brewer Diagnostic Kits

Complete Serological Screening Tests For Syphilis . . .

The RPR Card Tests make use of a specially prepared, carbon-containing RPR Card antigen. The particle size and other characteristics of the carbon is such that when a reactive specimen is encountered, flocculation occurs, and there is a coagglutination which is readily visible to the naked eye. Individual tests, including the collection of blood and separation of plasma can be performed in 7 to 8 minutes.

Confirming earlier findings with the RPR Card Test¹⁻¹⁰ Reed¹¹ in reporting on 63,800 specimens had an overall agreement of 98.5% in a recent comparative study with other routine screening procedures.

The RPR Card Tests, with their low cost, ease of performance, high sensitivity and specificity, are without peer in situations that demand rapid testing of patients, enabling the physician to initiate prompt treatment of early infectious syphilis.

Specify the RPR Card Test as the screening procedure on serum or plasma samples submitted to your State Approved Laboratory.

Current Attitudes in Otolaryngology

Doctor Lawrence Randall Boies will retire as Chairman of the Department of Otolaryngology of the University of Minnesota Medical School on July 1, 1967. In recognition of this occasion and to honor this leader in American Otolaryngology, internationally-known authorities in the field have contributed their views on "Current Attitudes in Otolaryngology." They dedicate their efforts in this Tribute Edition of MINNESOTA MEDICINE to Lawrence Randall Boies, M.D. — friend and most respected confrere.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views ex-

pressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers

Display advertising rates on request. Classified advertising rates appear on classified page.

Annual Subscription—\$6.50. Single copies—\$1.00.
 Foreign and Canadian—\$7.50.

Communications concerning advertising and subscriptions should be addressed to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Telephone CApital 4-5738.

Picture of bursitis

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.
Tylenol® (acetaminophen) 300 mg.

**Parafon Forte helps to relieve pain,
restore mobility . . . stop pain-spasm feedback**

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 6-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light-headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied:** Scored, light green tablets, imprinted "McNEIL"—bottles of 100.

President's Letter

THIS TIME I am really concerned. Since the advent of Medicare, there is developing a shortage of material for teaching purposes at the University of Minnesota Medical School. The patient who might formerly have been sent to the University Hospital is now being largely cared for in one of the many private hospitals in the state. This may be fine for the patients, but it is hard on the medical-school teaching staff.

It would seem to me that in this situation two birds might very well be killed with a single stone, as it were. The people of this entire country are faced with an acute shortage of family-doctor-type care. Recently there have been a spate of studies and reports, such as the Millis Report, the Health Manpower for Upper Midwest Report, and several other well-known studies on the same subject. All of them, without exception, have stressed the fact that there is a crucial need for not only more physicians, but especially more family physicians.

It is true that the ratio of physicians to population has increased over the past twenty years, but fewer doctors are going into private practice and more into research and other branches of medicine, which all adds up to a shortage of general practitioners. It seems to me that members of the private practice sector, as well as those on the University Medical School Faculty, could very profitably sit down together to work out mutual problems.

There are some faculty members who are enthusiastic about the production of greater numbers of family physicians; the great majority do, however, not appear to share

this enthusiasm. One thing is certain: more family physicians cannot be obtained from among the medical students by bribing, buying, or pushing them into this type of practice. They have to *want to go into it*. There must be motivation.

It would be my hope that the faculty could be so aware of their responsibilities to the people of this state that they would be eager to help motivate any of the students who showed an inclination for family practice, and that we could also enlist the volunteer assistance of that large group of residents in all fields of medical specialties, who have considerable association with and influence on the students. Is this expecting too much? Maybe so, but we hope the effort will be made. One of the most powerful motivations is precept, a method which has already been operating for years to induce students to go into specialty and research fields. So why not now partially reverse a hitherto successful procedure and urge more young doctors into family practice rather than into specialization.

I should like to suggest one way for increasing the number of patients entering the University Hospital for care and at the same time for providing a great deal more exposure to family type practice. It could be fairly easily determined how many family physicians would be required to provide sufficient referrals to the various departments within the medical school, so that sufficient teaching material could always be on hand. At least a start could be made toward developing a fairly steady supply of patients; and there would probably always be additional cases

Continued to page 1024

*"When I couldn't even smell corned beef and cabbage,
I decided it was time for you, Doc."*

Maybe he doesn't know when he's well off. But you might want to prescribe long-acting Novahistine LP anyway.

Two tablets in the morning and two in the evening will usually provide day and night relief by helping to clear congested air passages for normal, free breathing. Novahistine LP is formulated to provide continuous therapeutic effect for 8 to 12 hours. The decongestant ingredients help restore normal mucus secretion and ciliary activity—physiologic defenses against infection of the respiratory tract.

Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result. Each Novahistine LP tablet contains: phenylephrine hydrochloride, 25 mg., and chlorpheniramine maleate, 4 mg.

NOVAHISTINE® LP

PITMAN-MOORE Division of The Dow Chemical Company, Indianapolis

Editorials

Lawrence Randall Boies, M.D.

DOCTOR LAWRENCE RANDALL BOIES has occupied the pivotal position in Otolaryngology in the North Central United States for the past twenty-five years.

"Chance favors the prepared mind," and the quickened pace of medical progress in the past thirty-five years found Otolaryngology in this geographic area blessed by the presence of this one-man "steering committee." Organization and administration are a subtle art form to him. He accomplishes a great deal because he is not particularly concerned about credit as long as the work is done.

The history of the University of Minnesota Medical School currently in preparation will note that Lawrence R. Boies, M.A., M.D., was born in Renville, Minnesota, in 1898. He graduated from the St. Croix Falls High School in 1915 and entered the University of Wisconsin. His studies were interrupted by World War I when he served as a corpsman in the Medical Corps of the U. S. Army. Returning to the University of Wisconsin, he received a B.A. degree in 1922 and an M.A. degree in 1923 while the first two years of the medical course were being completed. In 1923-24 he taught for a year in the High School in Pipestone, Minnesota, and then entered the College of Physicians and Surgeons of Columbia University where he received an M.D. degree in 1926. After internship and nineteen months of practice as an assistant to a general surgeon in Minneapolis, he enrolled as a graduate student at Harvard Medical School. This period, including a residency at the Massachusetts Eye and Ear Infirmary, covered a period of twenty-five months.

Doctor Boies' great fortune came to him in 1928 when he married Louise Marty. They have had three sons: Doctor Lawrence R. Boies, Jr., Clinical Instructor in Otolaryngology at the University of Minnesota School of Medicine, who divides his professional time between instruction, research and the private practice of Otolaryngology in Minneapolis; David, a Yale Law School graduate, associated with the First Trust Company of Minneapolis; and William (deceased).

Doctor Boies was first appointed to the University of Minnesota Medical School faculty in 1931 shortly after he established a private practice in Otolaryngology in Minneapolis. He continued in private practice in Minneapolis until 1955, when he became the first full-time head of Otolaryngology at Minnesota.

Doctor Boies had been appointed Clinical Professor of Otolaryngology and Director of the Division of Otolaryngology in 1942 following the resignation of Doctor Horace Newhart because of ill health.

In 1943, subsequent to the resignation of Doctor Frank Burch, Doctor Boies was appointed Chairman of the Department of Ophthalmology and Otolaryngology. He worked toward the establishment of Ophthalmology and Otolaryngology as separate Departments. This could not be accomplished until funds, space and full-time leadership in Ophthalmology became available in 1955.

Doctor Boies' leadership qualities are evident in the positions of honor he has held in the local medical societies and the major scientific societies of American Otolaryngology:

Minneapolis Academy of Medicine (President, 1934).

Hennepin County Medical Society (President, 1944).

Minnesota Academy of Medicine.

Minnesota Academy of Ophthalmology and Otolaryngology (President, 1944).

Minnesota State Medical Association (Chairman, Committee on Conservation of Hearing, 1942-1952).

American Medical Association (Chairman, Section L.O.R., 1960-61).

American Academy of Ophthalmology and Otolaryngology (Board of Secretaries 1947-1956; President, 1962).

American Laryngological, Rhinological and Otological Society, Inc. (Vice President, 1946; President, 1957).

American Laryngological Association (First Vice President, 1966).

American Otological Society (Secretary-Treasurer 1956-1960; Vice President, 1961; President, 1962).

Board of Trustees, Central Bureau of Research 1951 to date.

American Broncho-Esophagological Society.

American Board of Otolaryngology (Director 1948 to date; President 1962 to date).

Fellow American College of Surgeons.

He is the author of more than seventy papers published in various journals, textbooks, etc. Along with faculty colleagues he is also the author of a textbook "Fundamentals of Otolaryngology," now in its fourth edition.

His public service includes service on the Special Medical Advisory Board to the Veterans Administration 1953-1957; the Communicative Disorders Research Training Committee of the United States Public Health Service, National Institutes of Health, and currently he is on the National Institutes of Health Communicative Sciences Study Section, Division of Research Grants,

of which he is Chairman.

Parallel with all general and special medicine, Otolaryngology has progressed and changed in the past twenty-five years. Participation in these changes has been an exciting adventure for the staff associates who have shared the years with Lawrence Boies. They find comfort that his "retirement" is in reality only a change of scene and perhaps of pace but not a dissociation from the medical arena he has enlivened these many decades. Doctor Boies retires as Director of the Department of Otolaryngology of the University of Minnesota School of Medicine and assumes comparable responsibilities as Executive Director of the Deafness Research Foundation headquartered in New York. A second career of service lies ahead.

Jerome A. Hilger, M.D.
Guest Editor
St. Paul, Minnesota

The Editor's Soliloquy

Homage

To the honor of the dedicatee of this issue MINNESOTA MEDICINE has introduced a deviation from its routine format in order to include manuscripts from a long list of willing and competent contributors.

Perhaps this is a unique innovation in medical journalism, and to that extent it is probably justifiable to ask: What do we want from the medical publications we pay for?

From our State Society do we want a journal of medical economics that teaches us how to build volume, collect bills, make investments, plan insurance? Or do we prefer a scholarly publication that will maintain and enhance our prestige.

Do we want our modern medicine in 60-second abbreviated abstracts embalmed between pages of distracting advertisements that offer too much volume and too little value? Or do we want a learned periodical which permits us to share vicariously the valuable experience of colleagues who have devoted clinical acumen to specific medical and surgical problems?

Do we want a bulletin that will provide us with details about meetings, with personality trivia included? Or do we want an erudite journal that will reaffirm and fortify our professional image as up-to-date practitioners, conversant with the current well documented literature.

Because it is believed that most of our readers want the latter of these several choices, MINNESOTA MEDICINE is herewith offering, not a complete list of vital statistics pertaining to the dedicatee, but rather an aggregate of monographs contributed by admiring and eager authors who welcome an opportunity to pay homage to their retiring chief.

Carl O. Rice, M.D.

Basic Research Contributions to Otology

MERLE LAWRENCE, Ph.D.*
Ann Arbor, Michigan

PROBABLY NO OTHER advance in Otology reflects the contributions of basic science more than surgery for deafness due to otosclerosis and for deafness due to chronic, eroding infections of the mastoid and middle ear. There are those today who maintain that basic science had nothing to do with the success of these procedures, that this is the result only of the insight of adventurous surgeons, but this is because these surgeons have knowledge they take for granted and do not realize the struggle that once took place to establish these seemingly obvious facts. So before the surgeons of the future become thoroughly imbued with the notion that it is their own courageous spirit that makes advances, it would seem appropriate to review some of these early contributions.

It was not always known that aerial vibrations were involved in the production and transfer of sound and, although air as a medium in which we live has "forever" been recognized, it has been only within the last three hundred years that air was definitely established as the necessary medium for the transfer of sound. And before any true knowledge of how the ear operates could be obtained, the characteristics of sound in air had to be discovered.

Galileo (1564-1642), often called the founder of modern physics, turned some of his ingenuity to the study of vibration and arrived at the significant conclusion that the important factor in determining pitch is the number of vibrations per unit time. He apparently arrived at this conclusion by an experiment in which he scratched a brass plate with an iron chisel. When the scraping produced a high-pitched note the intermittent scratches appeared close together while a low-pitched note produced marks farther apart. The manner in which vibration involved air in traveling through space was apparently very obvious to him. In his *Dialogues* he says: "Waves are produced by vi-

*Professor of Otorhinolaryngology and Physiology, University of Michigan Medical School and Director, Kresge Hearing Research Institute.

brations of a sonorous body, which spread through the air, bringing to the tympanum of the ear a stimulus which the ear interprets as sound." But still, this had not been proven by experiment, and so the issue was not really settled despite the respected authority of Galileo.

The Nature of Sound

It remained for two students of Galileo to find a way to produce a vacuum. In 1644 Evangelista Torricelli (1608-1647) reported his invention of the barometer. He died just three years after this brilliant demonstration, but another student, Viviani, carried on the experiments with new devices. Experiments in creating a vacuum were not taking place in Italy alone, however; an entirely different method was being employed by the Burgomaster of Magdeburg in Germany, Otto von Guericke (1602-1686). Von Guericke made the first air pump and performed the famous demonstration of the Magdeburg hemispheres.

Once air could be removed from a space it was possible to test the necessity for air in the transmission of vibrations. Such experiments were quickly performed and differed depending upon whether the vacuum was created by a Torricellian barometer or a von Guericke air pump.

In 1650 the Jesuit, Father Kircher (1602-1680), reported the first recorded experiment involving the sounding of a bell in a Torricellian vacuum. The bell was heard because, as we know now, the vibrations were carried along the supporting bar, and Father Kircher therefore concluded that air is not necessary for the transmission of sound. The problem was clouded still further when in 1657 the Accademia Del Cimento of Florence repeated Kircher's experiment and came to the same conclusion. Facts in science do not come easy!

It remained for Robert Boyle (1627-1691) to perform the crucial experiment in 1660. He evacuated a bell jar by means of an air pump and demonstrated that, with proper isolation of the bell, the sound did not travel through a vacuum. Subsequent experimentation led to the disclosure of the law

(Boyle's law) that the volume of a gas is inversely proportional to the pressure.

From this time on, experiments with sound took on real meaning. Measurements of the speed of propagation of sound in air, solids, and water were made, but the first serious attempt to theorize about the nature of sound was made by Sir Isaac Newton (1642-1727). He proposed a wave theory and described the propagation of sound as a series of pulses produced by the vibrating body. These pulses in the medium produce further pulses in adjacent positions of the surrounding medium and so the vibration moves outward away from the source. Thus the era of understanding the mechanical nature of sound began, and the voluminous research that followed has brought us to the concepts we have today that help clarify the acoustico-mechanical properties of the ear.

Auditory Physiology

While the physicists were debating and experimenting, the anatomists were slowly bringing to light the auditory structures that respond to air-borne vibrations. In 1777 Philipus Fridericus Meckel (1756-1803) furnished proof for the statement of Domenico Cotugno (1736-1822) that the inner ear contains fluid, not air, as had long been the belief. Meckel simply opened, under water, the inner ears of some cats and saw no escaping air bubbles, an observation that supported his earlier observation that frozen human inner ears contained ice crystals. It remained for such brilliant anatomists as Huschke, (1797-1858), Corti (1822-1876), and Retzius (1842-1919) to describe the fine structures of the inner ear and later for Wever and Bray¹ to record the electrical potentials that provided a powerful technique for the study of auditory physiology.

The Ossicular Chain

Although it seems so obvious today, the mechanical properties of the middle ear have been almost as difficult to elucidate as were those of air-borne vibrations. In 1683 Joseph Guichard DuVerney² (1648-1730) suggested that the round window might be an important route for the entrance of sound into

the inner ear, although he also recognized that the role of the ossicular chain is probably more important. The question was resolved, but still debated for over a hundred years, by the extraordinary German physiologist Johannes Müller (1801-1858), who numbered among his students the equally famous physiologist and physicist Hermann von Helmholtz (1821-1894). In his large handbook of physiology,³ published in 1840, Müller reports an experiment to demonstrate that vibrations are transmitted from air to a liquid much more effectively when a tense membrane and a chain of bones are the conducting media than when a tense membrane, air, and a second membrane conduct the vibrations. However, while this experiment demonstrated the important role of the ossicular chain, much further experimentation was necessary in order to demonstrate the role of the two windows in the ear and the mechanics of the membrane and chain of bones that enable them to be the most effective route.

Pressure Transformation

Many fine experiments must be skipped in this report, but certainly one of the most diligent investigators has been Georg von Békésy, winner of the 1961 Nobel prize in medicine and physiology (the first physicist to be awarded the prize in this category) for his work on the inner ear. Among many other experiments Békésy⁴ measured the over-all pressure transformation accomplished by the middle ear. A sound source was applied through a sealed conductor to the external meatus of a cadaver temporal bone and another source to the inner surface of the footplate of the stapes. The amplitude and phase of this latter source were adjusted until the effect of the two sounds, one through the tense membrane and chain of bones and the other at the footplate, immobilized the stapes. The ratio of the two pressures when the stapedia footplate remained at rest represents the pressure transformation of the middle ear which turned out to be a ratio of about 15 times.

Wever and Lawrence,⁵ by physiological means, considered the areal and lever ratios

in further detail. When Dahmann's⁶ figure for the lever effect of the peculiarly-arranged ossicular chain is added to the areal ratio between tympanic membrane and stapes footplate, the total advantage of the membrane and ossicular chain amounts to 25.5 dB, which is the amount of hearing loss to be expected as the result of a fenestration operation, or one in which the stapes remains after removal of the membrane and ossicular chain, and the round window protected.

The Era of Middle Ear Surgery

Surgery on the middle ear in cases of ankylosis of the stapes started in the final quarter of the last century based on the clinical observation, and on the knowledge furnished through experiment by Müller, that a freely mobile ossicular chain is necessary for normal hearing.

Surmounting Infection

Various degrees of success were achieved, not because of inconsistencies in the physical principles involved in the relay of sound to the inner ear, but because of subsequent infection and of the inability of the surgeon to visualize clearly the operative field. In 1928 the Scottish bacteriologist Sir Alexander Fleming (1881-1955) isolated the mold *Penicillium notatum* which exuded a substance capable of inhibiting bacterial growth. He called this substance penicillin but, being no chemist, he was unable to isolate or identify this substance further. Although the era of "wonder drugs" really began with the discovery of the bactericidal effects of the sulfa compounds in 1932 by Domagk (1895-1964), a German biochemist and winner of the Nobel Prize in 1939, the subsequent chemical isolation of penicillin by Florey and Chain, who shared the 1945 Nobel Prize with Fleming, and its successful use for war casualties in Tunisia and Sicily during World War II, introduced the age of the true antibiotics.

The Operating Microscope

The use of the microscope and the more recently developed antibiotics now make novel approaches to the surgical restoration

of hearing possible. However, the success of these procedures still depends upon practical knowledge of the mechanics and physiology of the ear, and the better schooled the surgeon is in these areas the greater his chances for successful advance of techniques.

Conclusions

We see today the bold onrush of surgeons to enter the realm of sensori-neural deafness. The activity is reminiscent of the late 19th century surgeons working in the middle ear. In the inner ear, however, we find different

problems; they are ones of hydrodynamics and biophysical chemistry. And we are today less advanced in our knowledge of this area than we were in our knowledge of middle ear mechanics at the time of Johannes Müller's experiments.

The same blundering paths may be followed, but certainly something could be learned from the past. A careful examination of the known facts and a concerted effort to fill in the gaps would be far more rewarding for surgical success than surgery first and a later guess at the basic mechanisms involved.

Yes, I Will Be a Doctor

On a blistering day in early August something happened, and the whole course of my future life was changed.

The oats had been cut by the reaper the day before and lay in loose bundles on a side hill which sloped toward the west. Working alone, I crossed and recrossed the field, binding these oats. The straw was dry and did not impart the coolness peculiar to freshly cut grain. The heat was oppressive and fairly scorched my face as I leaned over these parched masses of straw. At the end of a row I stopped momentarily in the shade of a thorn bush which protected the black jug of drinking water. Not a breath of air was stirring; it was almost suffocating. There was no comfort except in the movement of the body. At three o'clock it became unbearable.

Bordering the field was a country road. At that particular location there were a number of large, hardwood maples whose deep, dark shade protected the wagon track. As I straightened up to wipe the flowing perspiration from my eyes with the sleeve of my shirt, I viewed a scene from paradise.

Driving leisurely along the road in the shade of the maples was Dr. Daniel McLaren Miller, then the famous family physician of Oconomowoc. He was dressed in white linen, his buggy had a white canvas top and open sides, and the horse was protected by a white fly net that extended over its whole body, even to its ears. Before my eyes was a picture that brought joy to my soul and envy to my mind.

Instantaneously I dropped my rake and gazed until the apparition leisurely passed out of sight around the bend in the road. "Yes, I will be a doctor. Why haven't I thought of it before?"*

Surgery for Otosclerosis

HOWARD P. HOUSE, M.D.*
Los Angeles, California

THE HISTOPATHOLOGY of otosclerosis, or hardening of the ear bone, was described by Politzer¹ in 1887, as circumscribed bony protuberances that fixed the stapes in the oval window of the middle ear.

Historical

Meniere,² of vertigo fame, was the first to obtain temporary hearing improvement by manipulation of the ossicular chain. This was accomplished in 1842 by applying pressure on the malleus through the intact ear drum of a patient with probable otosclerosis.

Kessel,³ in 1894, was the first to perform mobilization and extraction of the stapes to improve deafness due to otosclerosis.

At the turn of the century, many otologists such as Boucheron,⁴ Miot,⁵ Moure,⁶ Passow,⁷ Blake⁸ and others were occupied in stapes surgery. Lack of adequate illumination and magnification hampered their ability to visualize the ossicular structures of the middle ear. Since antibiotics were unknown, otitis media and meningitis were rather common complications. Inasmuch as permanent hearing improvement was rare and the complications were severe, the surgery for otosclerosis by this method was largely abandoned.

Fenestration Operation

In the 1930s, surgery for otosclerosis was again revived by Sourdille⁹ of France and Holmgren¹⁰ of Sweden. The procedure developed by these men was known as the fenestration operation. Subsequently this operation was perfected by Lempert¹¹ of New York City. During the intervening years that followed the abandonment of stapes surgery, more accurate testing equipment (audiometers) became available. Improved

*Clinical Professor of Otolaryngology, University of Southern California.

From the Otologic Medical Group.

Sponsored by the Los Angeles Foundation of Otology.

illumination with the electric headlight and magnification with the two-power magnifying loop together with the introduction of sulfa drugs to control infection made more definitive otologic surgery possible. Lempert made use of all of these aids in perfecting his one-stage fenestration operation. This technique bypassed the fixed stapes by making a window in the horizontal canal of the labyrinth. The fenestration operation was a major surgical procedure requiring mastoid exposure, a week of hospitalization and two or three weeks of disability. However, it was successful in restoring permanent hearing in approximately 70 per cent of the cases.

Shambaugh, Jr. later introduced the Zeiss operating microscope to otologic surgery in the United States. This instrument is indispensable today in modern ear surgery.

The fenestration operation remained the accepted surgical procedure for the relief of otosclerotic deafness for some 20 years. In 1953, Dr. Samuel Rosen¹² of New York repopularized the stapes mobilization operation by applying modern instrumentarium to the previously abandoned stapes mobilization concept.

Although hearing could be improved by stapes mobilization in a high percentage of cases, this improvement was often of short duration due to regrowth of otosclerosis again refixing the stapes in the oval window area.

Stapedectomy

Recognizing that most of the otosclerotic regrowth involved the anterior portion of the stapes, Fowler, Jr.¹³ developed the anterior crurotomy procedure, which consisted of removing the anterior crus of the tiny stapes and mobilizing the posterior uninvolved portion of the stapes footplate. Although the operation was highly successful, the procedure was possible in only a small percentage of cases.

Shea¹⁴ attacked the problem by removing the entire stapes, placing a vein graft over the open oval window to seal the vestibule of the inner ear and establishing continuity with the incus by means of a polyethylene tube prosthesis. This procedure became

known as a stapedectomy and greatly enhanced the incidence of permanent hearing improvement. It soon became apparent, however, that slippage of the polyethylene tube would occasionally occur, sometimes with disastrous results if the tube entered the vestibule, thereby damaging the delicate inner ear structures.

To overcome the problem of polyethylene tube slippage, Hough¹⁵ devised the partial stapedectomy operation. In this procedure the anterior crus together with the anterior portion of the fixed footplate was removed, thereby allowing the posterior crus and the remaining uninvolved footplate to transmit the sound wave to the fluids of the inner ear. This procedure is in common use and is highly successful when fixation is limited to the anterior portion of the stapes footplate.

Schuknecht¹⁶ substituted a wire prosthesis for the polyethylene strut and used fat to cover the oval window area. Kos¹⁷ advocated wire and vein, and House²¹ wire and gelfoam.

The partial stapedectomy and the wire gelfoam technique are now widely accepted. Some surgeons (Shea,^{19,20} Guilford,¹⁸ McGee and others) use teflon or wire pistons as a stapes substitute and report very satisfactory results.

The Nature

Otosclerosis may be stapedial, involving only the stapes and oval window area (Figure 1); cochlear, involving only the inner ear mechanism (Figure 2); or both stapedial and cochlear. (Classification proposed by Shambaugh, Jr.).

The cause of otosclerosis is not known. The disease is hereditary, and patients with otosclerosis often have a positive family history of hearing impairment. Pregnancy seems to activate the progress of the disease in some cases. Otosclerosis involves both ears in some 80 per cent of the cases.

Diagnosis

Otosclerosis is characterized by a history of progressive hearing loss usually beginning in early adulthood and slowly progressing until the fifth or sixth decade when it seems to become more stationary. The hearing loss

usually progresses very slowly but at times may be quite rapid, especially during pregnancy.

The type of hearing loss is usually of a conductive or middle ear nature in its early stages; later the inner ear often becomes involved, thereby producing a mixed type of conductive and inner ear or sensori-neural impairment.

Loss of Low Tones

Characteristically the patient hears better in a noisy environment and tends to speak softly. This is typical of middle ear deafness since the low tones of noise are not heard as well as the higher tones of speech. Since the patient hears his own voice loudly, he compensates by speaking very softly. Chewing crunchy food such as celery or crackers sounds extremely loud to these patients; therefore their ability to hear is often greatly impaired at the dinner table. In this stage of the disease, the patient understands speech very well if adequate volume is presented. One can readily duplicate the dilemma of a patient with a conductive or middle ear type of hearing loss by simply plugging the ear canals.

Tinnitus

Tinnitus is common in patients with otosclerosis and may be most annoying. Again, the cause of this phenomenon is not known. Improvement in hearing either with a hearing aid or through surgery may diminish this symptom by simply producing more outside sound, which then tends to mask the patient's awareness of the "inside sounds."

Slight unsteadiness on motion may be elicited if careful inquiries are made of these otosclerotic patients. The instance of this symptom seems to be slightly higher in patients with otosclerosis than it is in the normal hearing individuals. Again the exact cause of this slight vertigo is not known.

As the inner ear becomes more involved, the patient tends to hear less well in a noisy environment and has more difficulty understanding speech even though adequate volume is presented.

Bone Conduction Better Than Air Conduction

The characteristic physical findings in otosclerosis is a perfectly normal ear and ear drum. Occasionally, one may observe a reddish hue due to increased vascularity. This finding is known as Schwartze's sign.

A 512 or 1024 tuning fork is heard better by bone conduction than by air conduction. Audiometric tests reveal a typical conductive or mixed type of pure tone audiogram. Speech tests reveal good ability to understand the spoken word when the volume is adequate.

The above tuning fork and audiometric tests are the typical responses of a patient with otosclerosis who has a conductive or even a mixed type of hearing impairment. As the inner ear becomes more involved, the tuning forks may become less definitive, the audiometer will reveal an inner ear or sensori-neural type of loss, and the speech tests will reveal decreased ability of the patient to understand the spoken word.

Conventional X-ray films may reveal sclerosis of the otic capsule. Laminagraphy or polytomography may reveal sclerosis involving the oval window niche and the stapes area.

Determination for Suitability for Surgery

The patient who is suitable for otosclerosis surgery is also suitable for a hearing aid. For either to give satisfactory hearing, the inner ear function must be reasonably good. If one cannot understand speech in spite of adequate amplification, it indicates excessive inner ear involvement and the patient is probably not suitable for surgery and will probably not accept a hearing aid.

Suitable Criteria for Surgery

1. He gives a history of progressive hearing loss of a conductive type: (a) he hears better in a noisy background; (b) crunchy food sounds loud to the patient; (c) he understands speech well when sufficient amplification is present.

2. He has a normal ear canal and ear drum.

3. He hears a 512 and preferably 1024

Fig. 1 — Temporal bone section illustrating stapedia otosclerosis. Note complete stapes footplate fixation.

Fig. 2 — Cochlear otosclerotic bone completely encapsulating the cochlea of the inner ear.

Fig. 3 — Fracturing the stapes crura.

tuning fork longer by bone conduction than by air conduction.

4. He has a conductive or middle ear type of pure tone audiogram.

5. He is in good physical health (age is not a contraindication).

Inner Ear Function

The extent of hearing improvement after surgery depends on the ability of the inner ear and hearing nerve to carry the sound to the brain. If the inner ear function is excellent, the patient may expect permanent restoration of serviceable hearing. If the inner ear function is moderately impaired, he may expect permanent restoration of serviceable hearing for near conversation but may need a hearing aid for distant communication. If the inner ear function is severely impaired, the hearing level may be permanently improved to allow better use of the patient's hearing aid (less volume and, therefore, less distortion). This type of improvement may also allow the patient to change from a body type of hearing aid to an ear level instrument. If the inner ear function is very severely impaired, the hearing level may be permanently improved sufficiently to allow the essentially deaf patient to hear some sounds with a strong hearing aid.

The degree of hearing improvement to be expected must be clearly explained to each patient depending on the amount of inner ear function that is present.

Surgical Technique

The operation is usually performed under local anesthesia and requires 20 to 40 minutes of operating time. The ear drum is elevated to expose the contents of the middle ear. The fixed stapes (Figure 1) is disarticulated from the incus, and the stapes together with the footplate is removed from the oval window (Figure 3 and 4) thereby exposing the perilymph in the vestibule of the inner ear. The oval window is covered with tissue or with gelfoam, and a prefabricated wire loop of proper length is placed in position and attached to the incus (Figure 5). A fibrotic membrane becomes enmeshed* in the wire and closes the oval window.

*See Test Your Word Score Page 1028.

Fig. 4 — Removing the stapes footplate from the oval window exposing the vestibule of the inner ear.

Fig. 5 — Compressed gelfoam over the oval window and insertion of the prefabricated wire-loop.

Sound vibrations are then transmitted directly to the fluids of the inner ear through the wire and fibrotic membrane (Figure 6). The ear drum is replaced, and the patient usually leaves the hospital the following morning and may return to work a week or ten days later.

Prognosis

In general, permanent hearing improvement can be expected in 90 per cent of the cases operated. Two per cent may be worse following surgery, and the remainder are essentially unchanged or slightly improved.

Complications

Certain complications may occur during or following stapes surgery.

Otitis Media

Middle ear infection may occur in spite of prophylactic antibiotic therapy in some 2 per cent of the cases. Ear pain develops and the ear drum may rupture. Early and adequate treatment usually resolves this problem.

Ear Drum Perforation

Occasionally a perforation may occur either as a result of infection or due to surgical trauma. Fortunately these perforations usually heal spontaneously without sequelae. If the perforation does persist, the opening may be closed by grafting (myringoplasty).

Fig. 6 — Reveals the prefabricated wire loop attached to the incus and enmeshed in the fibrotic membrane that covers the oval window.

Vertigo

Patients often have unsteadiness for several hours after surgery due to the opening of the vestibule of the inner ear. It is rare for this symptom to persist more than 24 hours. Occasionally some unsteadiness on sudden motion may be present for several months.

Further Hearing Loss

In 2 per cent of the cases operated and for reasons not clearly understood, the inner ear function may be impaired moderately or severely following stapes surgery. Because of this possibility, it is customary to operate on the poorer hearing ear.

Taste Disturbance

In some cases, an abnormal metallic taste may be present for several months after surgery, due to chorda-tympani nerve involvement.

Summary

The clinical diagnosis of otosclerosis is

based on the history of a progressive, conductive type of hearing loss without evidence of other ear pathology to account for this symptom.

Suitability for surgery can often be determined by the simple use of tuning forks and the patient's ability to clearly understand amplified speech. More definitive audiologic tests are always indicated before positive selection of cases can be made.

The stapes operation now permanently improves hearing in 90 per cent of the cases operated. The degree of the improvement depends on the ability of the inner ear to transmit the sound to the auditory pathways.

The complications of stapes surgery include otitis media, ear drum perforation, imbalance, taste disturbance and further hearing loss.

Conclusion

Today the patient with otosclerosis who has reasonably good inner ear function has an excellent chance of permanent restoration of hearing by modern stapes surgery.

Injustice

Whatever the human law may be, neither an individual nor a nation can ever deliberately commit the least act of injustice without having to pay the penalty for it.

— Thoreau

The Advantages and Limitations of a Hearing Aid

RAYMOND CARHART, Ph.D.*
Evanston, Illinois

A WEARABLE HEARING aid is an amplifying system designed to counteract the handicap of hearing loss by reproducing sounds at intensity levels strong enough to be useful to the patient. Clearly, a particular patient's success will depend upon three factors: (1) the adequacy with which his hearing aid reproduces sound; (2) the peculiarities of his hearing impairment, including any special problems he may have in interpreting sound; and (3) the kinds of everyday listening situations in which he must function.

Nature and Characteristics of Hearing Aids

Modern wearable hearing aids are usually of the air conduction type, consisting of five major parts: (1) a microphone that transforms sound waves into electrical patterns, (2) a transistorized amplifying circuit, (3) a battery that supplies energy, (4) an earphone that translates the amplified electrical patterns back into sounds, and (5) a hollowed earpiece that channels sounds to the ear drum.

Hearing aids do not achieve ideal sound reproduction for two reasons. First, crispness and clarity are restricted because the small size of the microphone and the earphone limit the range and the balance of the tones that are reproduced. Second, maximum output and amplification are limited not only by the instrument's small size and the problem of "squeal" but also because patients can not tolerate extreme sound levels. For these reasons the total intensity range that occurs in everyday sounds can not ordinarily be brought unmodified to the patient. When faint sounds are audible to him, the very strong sounds occurring an instant later will be distorted; while reducing the amplification to make

*Professor of Otolaryngology and Audiology, Northwestern University.

strong sounds more natural will make some of the fainter sounds too weak to be perceived.

A few hearing aids are worn on the body. These are used by persons who either need particularly powerful aids or have some other special requirement, such as the young child's need to have an instrument that he can wear comfortably and safely. More commonly, hearing aids are mounted at ear level, either in the temple piece of eyeglass frames or as a separate unit. Such a mounting has three advantages: (1) the microphone participates in head movement, (2) unnatural shadowing of sound by the body is avoided, and (3) the system is less cumbersome.

Indications

No patient gains practical benefit from a hearing aid unless many of the sounds he wishes to hear are otherwise inaudible to him. Ordinarily he must expect at least some trouble in direct conversation (when loss for speech is about 45 decibels). However, some people with milder losses spend enough time in restrained group conversations, business conferences and other faint listening situations to make a hearing aid useful at least on a part time basis.

Ordinarily, the upper limit of efficient use comes when loud speech close to the ear is barely understandable (when loss for speech is 75 to 80 decibels). Persons with still greater loss even miss a good deal of amplified sound. However, their need for the limited help they do get is tremendous, and there are very few people with losses so great that they can not find properly selected hearing aids of some value.

The Young Child

The young child poses a special problem in hearing aid use. Not only must he be taught how to wear a delicate instrument, but in addition, if he has a substantial hearing defect, he will need training to counteract the slower acquisition of auditory skill which his deprivation has caused. One can not place a hearing aid on such a child and expect full elimination of his

handicap any more than one could expect him to read Persian immediately if he were given eyeglasses. Parents in particular are often unrealistic, expecting miracles as soon as the hearing aid is put on the child, instead of realizing that listening skills can only emerge slowly by combining proper training before and after acquisition of the instrument.

The Elderly Patient

Elderly persons with mild losses present a very different problem. Here the loss in hearing is primarily for higher pitched tones. This loss disrupts intelligibility by reducing the crispness of consonantal sounds. Usually there is also a general slowing of auditory interpretative capacity because of aging. When these circumstances exist a hearing aid will be of only moderate help. As an amplifier it will make very faint conversation loud enough but will not restore the dulling of clarity caused by aging. Particularly important, it will be of almost no use in the noisy and chaotic environments which older people find especially disturbing acoustically. These limitations must be recognized and accepted if the typical elderly patient is to achieve any satisfaction with a hearing aid.

The Patient with Unilateral Deafness

Until recently the patient with unilateral deafness was not encouraged to wear a hearing aid. However, an arrangement known as CROS has changed this view. CROS picks sound up at the deaf ear and feeds it into the good ear through an ear-piece that is open enough to allow sound reaching the good ear directly also to enter it unhindered.

Limitations of a Hearing Aid

Three other considerations influence the value a patient will gain in everyday life from a hearing aid.

Environment

First, since a hearing aid functions only as an amplifier, it gives the greatest help when required to reproduce sounds generated faintly in relatively quiet environments.

The patient whose life habits carry him often into such circumstances will receive much more benefit than if he were in places where competing sounds are also being amplified.

Background Noise

Second, all background noise becomes relatively more disturbing in contrast to sounds of primary importance when heard through a hearing aid. Consequently, there are noisy environments wherein a normal auditor can still function effectively but which become unintelligible bedlam for the hearing aid user. Any person with normal hearing who is not fully aware of this problem will erroneously expect hearing aid users to understand well in any environment, no matter how noisy, where he himself can. Such lack of realism discourages and disgruntles hearing aid users. Such a user must come to know accurately those circumstances in which he should expect his instrument to be of help; knowing this he can take full advantage of its benefits without expecting the impossible from it. For example, a factory worker may find an aid completely impractical on the job and of little value when things get boisterous in the neighborhood tavern, but highly useful in church, during quiet conversations at home and the like. To demand that he wear a hearing aid all the time would be to nurture frustration.

Shadowing Effects

Third, the efficiency of everyday listening is greatly influenced by the shadowing effects which the body and the head produce effects especially marked when competing sounds are present. There will then be times when these competing sounds are not shadowed, while the sounds one wishes to hear are shadowed. The masking caused at such times by background noise can be as much as 12 decibels greater than masking in the reverse situation, that is, where only competing sounds are being shadowed.

No listener using only one hearing aid can escape at least some circumstances where the balance between background noise

and primary signal is made poorer because of shadowing. The problem is reduced with an ear level instrument because the head can be turned rather quickly so that the microphone is directed toward the primary sound, but it can not be fully eliminated unless two ear level aids are worn, one on each side.

With such a binaural arrangement, one or the other of the two hearing aids will be situated so that the primary sound is not shadowed and hence is being received through one ear with the minimum competition possible at the moment. In addition, binaural reception gives an added three decibels reduction in masking of speech by noise because both ears are being stimulated. Before deciding on a binaural hearing aid, however, one must weigh the benefits thus gained against the extra cost and added inconvenience of a second instrument. A drastically new level of overall efficiency in noisy situations will not be achieved simply by donning a second hearing aid. The binaural system is a tool of major clinical importance only because the wearer no longer must cope half the time with the added disadvantage of shadowing; but it does not deliver the miracles some expect of it.

Evaluation of the Patient

Obviously, *whenever a patient can use a hearing aid to practical advantage, he should do so.* To this end, he and all who advise him must be aware of the limitations as well as the advantages. Among other things his need should be individually analyzed by an expert in hearing disorders and in the use of hearing aids. Just going out and getting "any good hearing aid" is hazardous. For one thing there are subtle engineering differences which affect efficiency of models that superficially seem similar. Secondly, the instrument (or instruments) chosen must match his requirement as to power, amplification and tonal balance.

The task of guiding the patient to successful hearing aid use begins with careful otological evaluation, since a wearable instrument is the treatment of choice only when the patient's impairment can not be amelio-

rated medically or surgically. Also, the patient's auditory capacities must be analyzed by speech audiometry, including formal testing of his efficiency while wearing hearing aids chosen to meet his needs. The results of the entire examination, interpreted in the light of the patient's living habits and the other special considerations of his case, are the basis for deciding whether a hearing aid should be advised for him. If so, plans must be made at this same time for as extensive a program of guidance and training as his case may require. Such follow-up services range from brief advisory sessions with adults who can use amplifica-

tion easily to a prolonged educational program for the young child who must develop listening skills in conjunction with his mastery of hearing aid use.

Conclusion

In conclusion, hearing aids can be great boons to hard-of-hearing patients, but serious hindrances to their use often arise. These hindrances, however, can usually be overcome by appraising realistically what the patient may expect in the way of help and by giving him thorough professional guidance in the selection and use of an instrument suited to his needs.

William Clowes (1540-1604?)

That the times produce the man has been irrefutably demonstrated throughout history — but nowhere so patently as in medical history. When a challenge arose — it was met!

One such notable challenge was the treatment of gunshot wounds, which, in England's centuries of almost unrelenting warfare, presented multifarious problems unfamiliar to surgeons prior to the discovery and use of gunpowder.

One of the men who met the challenge was William Clowes, a sixteenth-century English army surgeon, whose wide observation and practice with soldiers wounded in battle resulted in the work, "Proved Practice for Young Surgeons," used as a reference and text by students. With what ingenuity and skill Clowes solved one troublesome problem is described in Parker's "Early History of Surgery:"

"In 1573 a soldier named Giles was shown him, who had been wounded three years previously in Flanders by a bullet entering the left iliac fossa. There was still a deep sinus there, which was seriously affecting his health, and the situation of the bullet could not be determined. Clowes made futile efforts to reach it by long probes. He then enlarged the orifice, introduced sponge tents, and even caustics, but he was still unable to get a flexible probe down to find the bullet. He bethought himself that a liquid might penetrate, and injected through a long tube a solution containing alum and sublimated silver, leaving it in while the patient was kept in a suitable position. Twenty-three hours after, pain and swelling began in the right buttock near the anus, which was poulticed. Next day he cut down on the swelling, found the bullet there, and removed it. After a series of dressings and injections the wounds healed up completely."*

Clowes, however, was not the only pioneer in the field of battle injuries; there were others. One might almost say that during her military history England produced a new breed of men — her military surgeons. Instigated by a drive to meet a new and compelling challenge, these men present convincing historical substantiation for the materialistic conception of history: the theory that the times produce the man.

Deafness in Young Children

JOHN E. BORDLEY, M.D.*
Baltimore, Maryland

MUCH HAS BEEN written in recent years concerning the deaf child, the ways to diagnose his handicap, his treatment, his rehabilitation and his prognosis. Unfortunately there is still much to be learned about children with such handicaps in spite of progress made through clinical research, pathological studies and experiments in rehabilitation in this field. In order that information can be gathered that is basic to early identification of the problem, it is necessary that the pediatrician and the general practitioner as well as the otologist be kept informed about the state of the art.

Communication

When one refers to a deaf child, one usually has the picture of a child with noticeable inability to communicate and to receive information compared to the average child of his chronological age. Communication difficulties are not necessarily due to deafness alone. There are many other factors that contribute to communicative problems in the growing child.¹

From the point of view of assembling the necessary data to make the diagnosis of hearing loss, it is of the utmost importance that all other conditions that may contribute to the child's communicative problem be identified or ruled out. Studies of a child suffering communicative difficulties should be undertaken as early as possible; therefore, the least suspicion of hearing loss or the failure to develop normal speech should alert the general practitioner, the pediatrician and the otologist to make an immediate investigation.

Causes of Difficulty

The most common causes of communicative difficulty in the young child of preschool age are: (1) hearing loss, (2) retarded

*Division of Otolaryngology, The Johns Hopkins University School of Medicine, Baltimore, Maryland.

mental development, (3) severe emotional disturbances and (4) aphasia. The child under observation, therefore, should not have his examination limited to hearing tests, but in any case where the hearing tests do not conclusively prove the handicap to be the result of hearing loss, psychological, psychiatric and neurological studies should be obtained. Many times such a battery of tests are not locally available, and it is necessary to refer children to medical centers for more definitive studies. One should always remember that children suffering communicative difficulties may also have multiple neurological handicaps.

History

Evaluation of the child should begin with a careful and complete history and be followed by certain basic examinations that can readily be made in the office of any clinician. The history which is of primary importance in these cases should include specific information in a number of areas. The areas outlined below will be of some use as a guide.

Family History

- The genetic background of the family
- The Rh factors of the parents
- Miscarriages or other obstetrical problems of the mother
- State of hearing and general mental and speech development of sisters and brothers in the family

Pregnancy

- Duration of pregnancy
- Prenatal infections, particularly those of viral origin
- Threatened miscarriages
- Unexplained fevers
- Drugs administered during pregnancy that might be considered ototoxic²

Delivery

- Onset of labor
- Duration of labor
- Position of child in uterus
- Use of forceps
- Type of anesthesia given to mother

Child's condition at birth particularly as related to cyanosis or evident trauma as a result of instrumentation. In the case of cyanosis, information should be obtained concerning aspiration, difficulty in starting respiration, duration of oxygen administered and length of time cyanosis persisted.

Development of jaundice in the newborn: degree and type of treatment

Postnatal

Health after birth and up until time of office visit

- Ear infections
- Head injuries
- Children's diseases
- Convulsive seizures
- Sleep patterns

Developmental History

Age of onset of sitting up, walking, climbing, self feeding, toilet training and speech.

A good yardstick by which to evaluate the development of a child is to remember that in normal children sitting up takes place at around six months, walking at around 12 months and speech development by the end of the second year.

Hearing

Much can be learned about hearing impairment by knowing a child's response to environmental sounds such as sudden loud noises, the sound of the doorbell and the ringing of the telephone. The child's reaction to being called from behind and from one room to the next should be ascertained and also his reaction to sounds of variable intensity such as the record player and radio. When possible it is helpful to determine *if a child understands what he is told or if speech merely acts as an alerting mechanism to get his attention.*

Speech and Language Development

Detailed information is important in this area. It has been noted in many instances that children who later develop communicative difficulties do not have a normal cry at birth or do not vocalize normally while

playing by themselves in their cribs. It has also been seen that children who do not develop speech many times fail to imitate sounds when playing with their mothers in early infancy. The language development which precedes speech really indicates the purposeful use of some sound. Language may start with the proper use of the sounds "da da" or "bye bye". It should be remembered that the sounds "da da" and "ma ma" are natural sounds made by the tongue and the lips during the growth of almost every child regardless of hearing or even brain injury. Unless these sounds are made purposefully they do not represent language or speech development. Once there is a beginning of language, speech development follows rapidly in the normally developing child. The child who does develop speech at a normal age but whose speech is difficult to understand is very likely to be a child with a partial hearing loss such as a high tone loss.

In reviewing the data assembled from a carefully taken history, it is very unusual for one to find a clear-cut picture pointing specifically and only to a hearing loss. This is because the child with a hearing loss will frequently give the impression of and a history that is compatible with mental retardation. In his frustrations he may also ape the brain-injured child, and in his inability to learn speech will simulate the aphasic. It is well to remember that the brain-injured child has a tendency to hyperactivity, destructiveness, and inability to join with the group in play situations. He has marked perseveration and an extremely short attention span.

Physical Examination

The second step in evaluating the deaf child is the examination. This starts with the ear, nose and throat and should be designed to establish the possible presence of foreign bodies in the ear, otitis media, perforations of the tympanic membrane, abnormal development of the external canals and the absence of normal landmarks on the tympanic membrane.

Hearing Tests

Following the ear, nose and throat examinations, simple hearing tests should be carried out. These can be done in the office very easily, using whispered voice sounds of ch, sh and k, calibrated rattles, sounds from a small xylophone and the sound of crushing tissue paper. All of these sounds elicit responses in the normal hearing child. A child of three months should turn toward the alerting sounds,³ all of which should be presented outside of the range of vision.

TUNING FORK

In cases of infants only a few weeks old, some information can be gained concerning their hearing or at least their reaction to sound by studying the moro response and the pinna reflex following sudden sharp sound stimuli.⁴ Much also can be learned by using a tuning fork. Such sound sources can be used equally well in infants and in young children. The tuning fork should be within the range of 500-1000 cycles so as not to transmit vibrations, and it should not be held too close to the orifice of the external canal.

It is important to remember that all hearing tests for children should be designed so as not to expose them to vibration, because their response to this can be confused with an auditory response. Coins or bunches of keys dropped on a wooden floor, or the use of large vibrating surfaces such as big pans can all give false responses.

OBJECTIVES

The primary objective of a clinical hearing test which can be done in the office is to identify some abnormality in the hearing. If such an abnormality is discovered it may be necessary to do a number of sophisticated studies which can be carried out only in a medical center in order to determine the type of hearing impairment and to rule out other conditions that simulate hearing loss.

HEARING CENTERS

Tests that are now becoming available in many hearing centers to enable a more

definitive diagnosis to be made are numerous. Those in most common use deserve a brief description.

CONDITIONING TESTS

The *peep show* in which a child is conditioned to receive an award if he signifies that he hears a test tone by some positive action such as pushing a button,⁵ and *galvanic skin resistance audiometry* where a child is conditioned by the use of a mild electric shock following the presentation of a sound stimulus.⁶ At first the skin resistance decreases following the shock; and after the child becomes conditioned, skin resistance drops following the sound stimulus in anticipation of the coming shock. Recent modifications of this test are now in use in which a single burst of tone is delivered at a fairly high intensity. No conditioning is employed, and the sound is not followed by a shock.⁷ The test can be repeated only a few times, however, before adaptation begins. In such a single burst galvanic skin resistance test thresholds cannot be obtained.

CORTICAL POTENTIALS

Evoked cortical potentials are now used to study hearing. In this test, *cortical potentials* evoked by a sound stimulus are picked up by electrodes applied to the skull.^{8,9,10,11} This test has been in use for some years. Recently using a summation computer technique, extraneous activities that are picked up by the electrodes are averaged out so that one is able to get an accurate impression of a child's auditory cortical activity. This test is now used to obtain near threshold levels of hearing. It does not, however, necessarily imply ability to understand speech. Much can also be learned by *free field* audiometry even in very young children. A sound-proof room helps to eliminate extraneous stimuli.

Final Evaluation

Combining all of these more sophisticated techniques with careful neurological, psychological and psychiatric examination, one is now able to learn a great deal about a child with a communicative disorder.

After the type of disorder and the degree of hearing loss is established, it is of the utmost importance to determine any contributing factors that may be ameliorated by surgical or medical measures. If the examination can identify the hearing loss as having a conductive type component, x-ray studies may be helpful.

Polytomograms* can demonstrate the presence or absence of ossicular chains. They can also show deformities of the round and oval windows and abnormalities of the bony cochlea.

Such surgical procedures as the construction of an external canal, the creation of a functional ossicular chain or the simple removal of the adenoids should be carried out before any decision is made on the training program.

Following any such corrections hearing tests should be repeated to establish the basic hearing loss. When this has been determined consultation should be begun with the family to develop a long-range program.

Hearing Aids

In almost all the cases where children have a hearing loss, the question arises as to the advisability of the use of a hearing aid, and the question that follows is, "At what age should a hearing aid be selected for a child?" In general, when a child suffers from a conductive hearing loss, if such a loss is bilateral, a hearing aid should be selected and it should be quite helpful. Those children suffering sensori-neural hearing loss face a much more difficult problem.

The use of a hearing aid in the child with distorted hearing will be more successful than in an aging adult, but it still leaves the child with defective speech; and if the low tones are near the normal line, the child may reject the hearing aid because of the intensity of the low tones which cannot be sufficiently suppressed when high tones are being magnified.

The child who rejects his hearing aid should be studied very carefully. The first thing, of course, that must be determined is whether the ear mold contributes to his discomfort and for this reason, he rejects

*See Test Your Word Score Page 1028.

the aid.

Alerting Mechanism

In children with severely debased hearing of a sensori-neural type, one should consider the use of an aid as an alerting mechanism rather than with the idea of restoring the threshold of hearing to a near normal level. It is extremely important with young children that they learn to associate some sort of sound with human communication even if it is only enough sound to alert them to turn their heads so that they may see the speaker.

Age to Use Hearing Aids

Hearing aids should always be used at as early an age as possible; in many instances, this seems to be between the ages of one and two years. If possible some evaluation of the type of hearing loss and the degree of loss should be established before an aid is fitted. As a rule of thumb most children who profit from the use of an aid, and this may include those extremely deaf children mentioned above, will accept the aid and show no objection to its daily use.

Children who, due to distorted hearing or extreme sensitivity to sound are made uncomfortable by loud sounds being introduced into the ear by the aid, will soon reject it. The decision to use the aid should be left, of course, until all other studies have been completed. The aid should be chosen and fitted with great care by a trained audiologist with a good clinical background.

Home Training

In general it is the consensus of opinion among teachers working with the handicapped-hearing child that where the hearing loss is not so great as to demand complete special training, it is better to keep the child in the home environment and enter him in a normal school situation, taking advantage of special preschool training that is available and the special instruction that can be obtained in a normal school program today.

In the home, especially when there are

normal brothers and sisters living with the hearing-handicapped child, conditions are better for the social and emotional development of the child.

As part of a young child's education, use should be made of home guidance courses such as the John Tracey course. The Tracey course has an added advantage in that it is of great help to the parents.

When a program is outlined, it has been the experience in this clinic that the parents need regular counseling to review with them all the advances made, all the problems still existing and the steps that must be made for further rehabilitation.

Conditions Predisposing to Hearing Aids

It should be remembered by those physicians caring for young children that a number of conditions predispose to hearing loss. Any child born following a prenatal viral infection,¹² be it rubella or any other type of viral infection, should be watched and should have his hearing thoroughly checked by the age of a year and a half to two years. Children born with erythroblastosis or with a history of a long period of cyanosis following birth should be suspect.¹³ The incidence of neurosensory hearing loss is very much higher in premature children than in full term children. Many children have hearing problems of the less severe variety due to some degree of middle-ear disease. Early recognition of such lesions is important in order to correct the lesion before it becomes irreversible.

Speech Development

It should be emphasized again and again that when a child fails to develop speech at the average normal age for speech onset and when he fails to give normal responses to sound stimuli, he should be investigated very carefully. If he is deviant in other ways as well as in his hearing responses, he should have further examinations to rule out other neurological defects. The problem facing the world today is one of early identification. It is up to the general practitioner, the pediatrician, and the otologist to have a high

index of suspicion and to insist that these children have a careful and complete evalua-

tion of their hearing at as early an age as possible.

Heart Diagnostics in Ancient Egypt

The Scribe of the ancient Egyptian Papyrus dealing with medicine was evidently cognizant of the physiological-emotional reactions of the human heart. He appears to have been sure of himself; neither incertitude nor inhibition is detectable in his naive and rather touching exposition:

When anger arises in his heart, behold it is a seething-up of the parts of the Intestine and the Liver. His Ear is on the alert, his vessels fall after their rising heat has dissolved everything.

When the Heart is sad, behold it is the moroseness of the Heart, or the vessels of the Heart are closed up in so far as they are not recognizable under thy hand. They grow full of Air and Water.

When the Heart feels an aversion, behold it is the Bitterness of the Heart because of Inflammation in the Anus. Thou findest it big and something forms itself in his Abdomen as in his Eye.

Praise from a Scholar

Antiquity rightly both believed and proclaimed that no reward worthy enough can be paid to a skilled and trustworthy doctor . . . The theologian makes men repent of their sins, but it is owing to the doctor that there is anyone to repent. It is vain to be a physician of souls if the soul for whom the antidote was prepared has already fled . . . We owe gratitude to those who drive off the enemy who flies at our throats; are we not more indebted to the doctor who daily fights for our safety against the mortal enemies of life? — Erasmus (1466-1536)

Principles in Rhinoplasty

IRVING B. GOLDMAN, M.D.*
New York, New York

SUCCESSFUL RHINOPLASTY is based on anthropology, physiognomy, genetics, diagnosis, physiology, psychological therapy, anticipated healing properties of the tissues, and art anatomy with appropriate esthetic appreciation. The deformity must be studied, the nose properly analyzed, and the general facial impression noted. All the above mentioned components must be integrated before surgery. The surgeon must deliberate upon what he wishes to do, but what is more important he must consider what potentials are involved in obtaining a satisfactory result.

Indications for Rhinoplasty

As one becomes experienced in rhinoplasty, it becomes apparent that trends change from the viewpoint of esthetic results as well as surgical techniques.

Esthetic

The geographical habitat of the individual has a direct bearing on the overall indications for corrective rhinoplasty, as well as the desired cosmetic result. The primary motives for those seeking a rhinoplasty are unchanged; the esthetic, functional, and especially the psychic still prevail. Function is important, but those seeking a rhinoplasty will frequently use this medium as a subterfuge because they do not like the appearance of the nose. It becomes obvious that nasal dysfunction, so common in many people, is merely the starting point for demanding a cosmetic operation. Obviously, a badly disfigured nose is often accompanied by a severely deviated septum; but the majority of those seeking a rhinoplasty have minimal septal abnormalities.

Functional

Some rhinoplastic surgeons assert that

*Consulting Rhinoplastic Surgeon, Department of Otolaryngology, Mount Sinai Hospital, New York and Emeritus Associate Clinical Professor, Department of Otolaryngology, Columbia University.

Reprint requests to 121 East 60th Street, New York, N. Y. 10022.

they carry out septal resection or reconstruction in 75-80% of their patients. Others do it routinely to prevent constriction of the airway by the infractured lateral nasal walls. One has only to experience a nasal collapse after performing these combined procedures to recognize and respect the stabilizing function of the septum. Excessive sacrifice of the septum and subsequent loss of support of the dorsum, in addition to the frailty of the nasal structures because of loss of stability of the underlying septum, should induce the surgeon to ponder before he weakens that formidable structure. The septum operation that I have sponsored for many years, namely minimal removal and replacement, still prevails today. Many nasal complications are caused by the loss of the supporting role of the septum. In a combined rhinoplasty and septal reconstruction, partial or total collapse of the nasal pyramid may result from loss of support of the scaffolding septum after osteotomy of the nasal walls and mesial shifting of the nasal processes.

Surgical Management

Proper prophylactic management of the obstructing septum and specific technical steps must be undertaken to prevent dropping of the residual nasal bones and lateral nasal processes as well as the upper lateral cartilages, which can produce a saddle of either the osseous or cartilaginous vaults or both. Roentgenograms taken of such complications of total collapse show these vaults to have fallen almost into the floor of the nasal chambers.

The Anesthesia

Apprehension of needle injections for local anesthesia is widespread. Patients are advised that the operation is painless but that the solution must be injected for anesthetic as well as hemostatic purposes and for aiding undermining of the nasal integument. Some surgeons use inhalations of trichloroethylene to dull the consciousness before the anesthetic is injected. I have been using a Panjet syringe initially, preparing the regions for deep penetration when the local anesthetic is injected. As a result, the com-

mon complaints about painful needle injections have almost completely disappeared. The Panjet compresses a 1/10-cc. volume of anesthetic solution and, when the release button is depressed, emits the compressed liquid in the form of a fine jet spray which penetrates the surface to a controlled depth of 2 to 6 mm. No needle is used and the controlled region of perfect subtopical anesthesia is painlessly achieved. Painless wheals are raised through which the needles are inserted. Some anxious patients insist on intravenous demerol for the rhinoplasty. I agree to the intravenous demerol or similar drugs but, in collaboration with the anesthetist, the intravenous anesthesia is kept at a minimum because of the preliminary local anesthesia with the Panjet syringe. The complications from intravenous demerol and the long periods of unconsciousness following the operation have been eliminated by the diminished intravenous dosage.

Mesial Osteotomy

After hump removal the mesial osteotomy, usually by a chisel, is carried out in order to facilitate symmetrical mesial shifting of the nasal pyramid to the midline after the lateral osteotomy. By this pressure impact on the lateral nasal wall the nasofrontal articulation is severed. Many of the pioneers in rhinoplasty avoided the mesial osteotomy; others objected that a low fracture would result, producing a wide radix. This may be true, but the lateral walls of the radix are readily amenable to instrumentation, producing the desired normal width of the bridge of the nose. The mesial osteotomy causes a loose or frequently comminuted fracture after lateral osteotomy and mesial shifting of the nasal bones and processes. Avoidance of the mesial osteotomy results in a more stable osseous pyramid after infracture. Protruding bones on either side of the root of the nose can be easily smoothed by the fine rasp or under direct vision by the bone clipper. Obviously, if a nose is very broad because of wide nasal bones and radix, mesial osteotomy is required to remove wedges of bone for closer approximation. Under these circumstances the integument

and procerus muscle help camouflage smaller bony irregularities which may be difficult to smooth or level because of their extreme mobility.

To help avoid the mesial osteotomy I have found it expedient to shave the most superior ventral thick block at the radix. Frequently after the hump has been removed, a slightly elevated bony dorsum can be seen and felt cephalically. To reduce with safety this shallow but thick bony projection to the proper profile line I have devised a "plane" chisel. The upper dull prong rests on the bones as a protection against removing too much bone. The cutting chisel is attached beneath and slightly posteriorly. Depending on how much the "plane" chisel is angulated, one may remove bone dust or 1 mm. of the solid bone at the nasal root. This bony removal also helps to narrow the nose after mesial shifting of the frontal nasal processes which fracture high or very close to the nasofrontal articulation. To lower a high nasofrontal angle the "plane" chisel can be reinserted and more bone removed safely (Figure 1).

Modeling the Tip

As we discuss modeling of the tip it becomes apparent that the mesial crura are the salient factors in tip projection and in tip rounding or drooping. The parts of the nasal tip to be modeled include the columella which is in line with the height of the nostrils, the lobule, the structure above the

nostrils reaching the apex of the tip, the nasolabial angle, and the slope of the nostrils. These definitive structures can be modeled only if the entire lower lateral cartilage extending into the lobule is completely freed from the overlying skin. Naturally this requires more time, skill, and patience. The tip which I have described fulfills all requirements for precise modeling. The low columellar sutures will bring about the desirable nasolabial angle. The freed, bisected and sutured mesial crura will help model the lobule, give the required projection, influence the slope of the nostrils and produce the desired "double break" which takes place between the straight or slightly curved columella and the angulated lobule. A tip is produced that not only looks good on the operating table but retains its appearance permanently.

The Age Factor

In young patients the lower lateral cartilages are very frail, thin and underdeveloped. After surgery they may heal with a fibrous tissue curtain resulting from contact between the extremely thin and loose lower lateral cartilage and the septum. I have been consulted by patients who were operated on at age 12 and revised at age 13, in whom an artificial cul-de-sac completely occluded the nasal vestibules. I believe that the opportune age for a rhinoplasty in young patients depends essentially on the degree of development of the lower lateral cartilages. Mani-

Fig. 1 (A) — Side view of "plane" chisel from above; (B) Lateral view showing dull protecting blade superior to cutting chisel below; (C) "Plane" chisel from above. Photographs are enlarged.

festation of firmness of the cartilage on palpation serves as a criterion for carrying out a suitable rhinoplasty. The cartilaginous rigidity begins to manifest itself after 15 or 16 years of age. At an earlier age removal of the cartilage not only may cause nasal obstruction or alar collapse, but can also produce a poorly corrected tip because its immature skeletal composition lacks molding adaptability especially of the mesial crura which serve as the fulcrum for the new tip. Healing of the overlying skin is unpredictable.

Conclusions

The principles of rhinoplasty have been modified by the changing esthetic objectives

of the patient as well as of the surgeon, and by advancements in the technical approaches. Much can be done in order to obtain a natural, normal functioning, non-surgical appearing nose. Where the perspective is unattainable the rhinoplastic surgeon must abstain from performing esthetic surgery. The overly ambitious who have attempted impossible procedures have learned to use better judgment in the screening of patients for corrective nasal surgery. In cosmetic rhinoplasty the surgeon should learn to distinguish between the favorable and unfavorable variety of patients in order to obtain the most satisfactory results. Mediocrity is no longer acceptable.

The Frontier Doctor III*

At the end of a long and wearisome ride, the doctor set broken limbs, bound up wounds and injuries, delivered babies, fought smallpox, pneumonia, and diphtheria. His cures were blunt. He slit the throat of a child choking with diphtheria and opened the windpipe. He kept the aperture from closing with fishhooks. A frontier doctor's cures were vigorous too. Seizing a patient sick with fever, the doctor opened a vein and drew blood until unconsciousness was near. This lowered the heart action. The patient broke into perspiration. His fever and delirium vanished. The doctor next administered tartar as an emetic and followed it with a calomel purge. Finally he "locked the bowels," as the expression went, with opium. When the doctor paid a return visit, the patient usually declared himself "well, if a little weak," most likely to prevent additional treatment. The doctor was ingenuous too. If a man broke his leg, he reduced the fracture and tied rough-hewn shingles on each side of the break. To keep the leg pulled straight, he constructed a traction apparatus with a rope and a flatiron or a few horseshoes.**

A Physician's Voice from Ancient India

By the sense of *hearing* we can, for instance, determine whether the contents of an abscess are frothy and gaseous, for the emptying of such is attended with noise; by the sense of *feeling* we may know whether the skin is hot or cold, rough or smooth, thick or thin; by the sense of *sight* we can determine corpulence or emaciation, vital power, energy, and change of color; by the sense of *taste* we can assure ourselves concerning the state of the urine in diabetes and other diseases of the urinary tract; and by the sense of *smell* we can recognize the peculiar perspiration of many diseases which has an important bearing on their identification.

— Susruta (6th Century B.C.)

Diseases of the External Ear

Current
Status

BEN H. SENTURIA, M.D.*
St. Louis, Missouri

DISEASES OF the external ear occur in 5% to 10% of patients seen in a general ear, nose and throat office practice. Preventing diseases of the external ear is difficult; however, some factors contributing to the development of some of these diseases are known.

Classification

The author, in collaboration with M. D. Marcus in 1952, published a classification of diseases of the external ear which incorporates dermatologic as well as otolaryngic concepts and principles. This increasingly accepted classification, modified to incorporate some of the more recent developments, is as follows:

Diseases of Unknown Etiology

- A. Malfunction of Skin Glands
 - 1. Seborrheic Dermatitis
 - 2. Asteatosis (Dry Ear)
 - 3. Hyperceruminosis
- B. Infantile Eczema
 - 1. Infantile Intertrigo
 - 2. Infantile Dermatitis
- C. Membranous External Otitis
- D. Chronic Idiopathic Myringitis
- E. Lupus Erythematosus, Psoriasis, etc.

Diseases Due to Infections

- A. Bacteria
 - 1. Gram-positive
 - a. Furunculosis
 - b. Impetigo
 - c. Pyoderma
 - d. Ecthyma
 - e. Cellulitis
 - f. Erysipelas
 - 2. Gram-negative
 - a. Diffuse External Otitis
 - b. Bullous External Otitis
 - c. Granular External Otitis
 - d. Perichondritis
 - 3. Acid-fast

*Associate Professor of Clinical Otolaryngology, Washington University School of Medicine.

B. Fungi and Yeasts (Otomycosis)

1. Saprophytic
2. Pathogenic

C. Virus

1. Bullous Myringitis
2. Herpes Simplex
3. Herpes Zoster
4. Molluscum Contagiosum
5. Variola and Varicella

D. Protozoa

E. Parasites (Animal)

Neurogenic Eruptions

A. Simple Pruritis

B. Neurodermatitis

1. Localized
2. Disseminated

C. Neurogenic Excoriations

D. Artifact Dermatitis

Allergic Dermatoses

A. Contact Type Dermatitis (Dermatitis Venenata)

B. Atopic Dermatitis

C. Drug Eruptions

D. Infectious Eczematoid Dermatitis

E. Physical Allergy

Traumatic Lesions

A. Contusions and Lacerations

B. Surgical Incisions

C. Hemorrhages

1. Hematomas
2. Vesicles and Bullae

D. Trauma

1. Burns
2. Frostbite
3. Radiation Injury
4. Chemical Injury

*Senile Changes**Vitamin Dyscrasias**Endocrine Dyscrasias***Etiology**

Convincing evidence exists from human and animal investigation, that gram-negative bacilli are more common in the diffuse external otitis type of infection while gram-positive organisms are found in the eczemas, furuncles, etc. Of course, fungi continue to be the most important agent in the otomycotic lesions. Temperature and humidity are now thought to play an important role in the incidence of diffuse external otitis; but less understood are the roles of skin lipids, excessive sweating, stress, and anatomical configuration in the causation of these diseases. Likewise, PH of the ear secretions and allergic factors are poorly understood etiologically, but little evidence exists to confirm these as important factors in the causation of non-allergic external otitis.

Treatment

Unfortunately, there is a tendency to give the same "shot-gun" prescription for all forms of external otitis. A common mistake is that of giving penicillin injections and ear drops in an oily vehicle for typical diffuse external otitis infections due to an overgrowth with gram-negative bacilli. Serious, resistant infections with irreversible sequelae may result from this error. Oily drops are also contraindicated in acute diffuse external otitis; drying and soothing agents are a better treatment.

Eyes are compacted powers; they are an index of vision; they see and refer us to greater seeing. Nor has the stomach a less noble office. It digests food; that is, in its own particular method, it deals with the nourishment offered by the universe. It is the physical formula of that health which destroys certain elements — the bacteria which harmfully approach us. By it we learn to consume; by it therefore to be, in turn, consumed. So even with those poor despised things, the buttocks. There is no seated figure, no image of any seated figure, which does not rely on them for its strength and balance. They are at the bottom of the sober dignity of judges; the grace of a throned woman; the hierarchical session of the Pope himself reposes on them. — Charles Williams

Plastic Surgery of the External Ear

RICHARD T. FARRIOR, M.D.*
Tampa, Florida

THE GENERAL PHYSICIAN has become increasingly aware of the need for correcting deformities of the external ear and increasingly informed regarding some of the surgical procedures available, which he might recommend to his patient. Deformities of the external ear, for our purposes in this presentation, are divided into two general groups: first those involving the simple protruding ear, and second, those requiring more extensive reconstructive surgery with or without the loss of tissue.

The modern otolaryngologist is intimately familiar with the anatomy and all diseases of the external ear and is trained in the reconstructive procedures of the auricle and external canal.

The Protruding Ear

Medicine generally has come to accept the value of esthetic procedures in the improvement of the overall well-being of the patient, particularly in these times when a premium is placed on appearance and the stresses of the modern age make it desirable to reduce the deleterious psychological effects of a deformity when this is at all possible.

The deformity of the protruding ear, more than others, fosters a reaction of mirth from other people, instead of inciting sympathy as with other deformities, and the child is constantly reminded of his defect. The adjustment an adult may have to uncorrected protruding ears is influenced by his individual personality, but even most adults in honesty to themselves do not like their protruding ears. Most are very keenly aware that the ears they are endowed with may interfere with their personal relationships, both economic and social. The deleterious psychic effects make these deformities of clinical significance.

Emphasis is placed on the normal contour

*Senior attending in Otolaryngology and Maxillofacial Surgery and Plastic Surgery, Tampa General Hospital.

of the ear as seen from the side. There are numerous procedures for correcting the protruding ear, but many have shortcomings in terms of recreating exact contour. The modern otolaryngologic plastic surgeon should be precise in his technique and attempt to mimic nature as accurately as possible.

Operative Procedure

The operation for correction of protruding ears may be performed under local or general anesthesia and produces minimal discomfort or morbidity. For the psychological reasons discussed, it is beneficial to have the operation performed by six years of age; however, many operations are performed in adults. Most patients are in the hospital only overnight. A splinting ear dressing is worn for from five to seven days.

The Antihelix

Luckett, in 1910, first emphasized that the antihelix was the primary area involved in the abnormally protruding ear. Many operative procedures have been developed, designed at either breaking or weakening the cartilage spring and creating a normal angulation of the ear. As seen from the side many of the procedures create abnormal angulation or visible incisional lines which are distracting. The late Doctor Oscar Becker contributed as much as any one man to the modern concepts of analysis of the deformity and attention to details.

The technique I developed is aimed at creating normal contour with predictable results, and it incorporates techniques which take into account all the many variable anatomic factors which contribute to protruding ears.

Technique

The technique includes both breaking the cartilage spring by carefully placed incisions about the inferior portion of the antihelix and weakening the spring by the removal of longitudinal cartilage wedges which do not create abnormal angulations on the anterior surface. The latter is particularly important about the superior crus. These re-

moved longitudinal cartilage wedges do not extend through the thickness of the cartilage.

The technique as mentioned takes in all contributing factors in the production of the protruding ear even though all may not be involved in a particular case. By following this technique the young surgeon is less apt to create disappointing results.

Suturing Technique

In recent years the simple suturing technique has been repopularized and, has given satisfactory results particularly in young children with delicate cartilage, provided the normal anatomy is critically analyzed in regard to placing of the sutures. In the simple ear in young people without too much cartilage resilience and not too deep a conchal cartilage, the simple technique may work.

Problems

The simple suturing technique does not take into account all factors contributing to the particular deformity. Among these we would have to consider:

A pillar effect of the inferior crus is sometimes encountered.

Success depends upon the degree of the existing convexity of the antihelix, the degree of the existing concavity of the scaphoid fossa, and the development of the antihelix. With the simple suturing technique there is a backward tilting and flattening posterior to the antihelix which may occur in a flat ear where there is no scaphoid fossa and minimal helical rim. The suturing technique does nothing to create the scaphoid fossa.

Nothing in the simple suturing technique accounts for the deep cupped conchal cavity where it is essential to remove some cartilage to reduce the cup. It is interesting that since the revival of the simple suturing technique many surgeons are now adding modifications and are facing up to more complicated procedures. This results from improper analysis in some cases of the contrib-

The author emphasizes normal contour as seen from the side. Note the gradual convexity of the superior crus blending with the fossae on either side, the continuous blending of the crura with the antihelix proper, the acutely convex antihelix proper gradually widening superiorly, and the definite scaphoid fossa. Normal projection with the preservation of the auriculomastoid angle is obtained.

uting abnormalities.

In summary, our technique is perhaps more complicated for some ears; however, it takes into account all factors and all possible pitfalls.

Reconstructive Procedures

Apart from the simple protruding ear, deformities of the external ear may be divided generally into those with and without the loss of tissue. Only soft tissue may be involved or there may be a loss of cartilage framework.

The nature of the thin, relatively adherent skin on the anterior surface of the ear, and the contoured and delicate, yet definitely supporting cartilage present major problems in reconstruction. Without loss of tissue, surgery usually involves excision of excesses or rearrangement of the existing skin or cartilage. It may be necessary to elevate the surface of the skin, refashion the existing cartilage, and then redrape the skin in the new contour.

The most common deformities are those with defects and loss of tissue. The absence of soft tissue or cartilage may be the result of congenital anomalies, trauma with avulsion, or surgical defects usually excisional for carcinoma.

Although blood supply in general is good, reconstruction of the surface layers and the intervening and supporting cartilage keeps the surgeon in a critical state of balance between viability and esthetics. The latter usually suffers to some degree.

Congenital Anomalies

These deformities may range from simple preauricular appendages or fistulas to total absence or severe microtia* with stenosis or atresia of the canal. The surgeon must present an honest and frank appraisal to the parents or to the older patient. The limitations of the final results in total reconstruction, the number of stages, and the psychological aspects of the surgery itself should be outlined and the patient allowed to make the decision to proceed.

If one is honest in his presentation, he frankly finds himself with few total reconstructions to do. These are done with fair success, serve the purpose of eliminating the need for a prosthesis, and provide an ear constructed from the patient's own tissue. Recent attempts in a significant series, utilizing the silicone rubber pre-made framework, have in the majority of cases proved disappointing and in one way or another have presented or required eventual complete removal and replacement with autogenous cartilage. The repair should be closely correlated with the indications and techniques for middle ear surgery.

Traumatic Surgery

Traumatic surgery requires careful closure in layers of lacerations through the cartilage. I see no objection to approximating the cartilage with sutures through the thickness of the cartilage, although this continues to be frowned upon by some. Retrieved, avulsed portions of the auricle should be thoroughly cleaned and delicately sutured in position to produce accurate approximation without impairment of the blood supply. Major loss requires the same consideration as for excisional defects for cancer.

Carcinoma

Carcinoma of the external ear requires vigorous excisions, staying one jump and one natural tissue barrier ahead of the lesion. If cancer of the external ear extends to the mastoid bone, the prognosis is grave. Where the skin is mobile, the underlying cartilage and bone should be excised. With bone or periosteal involvement en bloc, radical resection is essential. Small marginal defects may be treated by x-ray or electrodissection, but these defects are also readily excised and repaired, thus avoiding x-ray over the auricular cartilage.

Repair of Large Defects

Repair of larger defects in most instances requires the use of the postauricular sulcus skin or skin over the mastoid process. A

*See Test Your Word Score Page 1028.

pocket may be fashioned to receive salvaged auricular cartilage or an implant for reconstruction of the framework. This pocket is utilized to transfer skin to the anterior surface of the ear. For smaller defects I have had some success with homogenous preserved cartilage, polyethylene or silicone implants; but I have stayed with autogenous costal cartilage for major reconstructions.

The postauricular skin may be used in a variety of ways as advancement and rotation grafts. If tubed pedicle grafts become necessary, these can more often be fashioned in the periauricular area or from the immediately adjacent cervical skin.

Ear Remnants

All possible remnants of the ear should be saved, either to aid in reconstruction or for the attachment or support of a prosthesis. Some reconstructive procedures may be necessary simply to aid in the wearing of a prosthesis. Where some portion of the ear remains, reconstruction has much to offer. As mentioned, total reconstruction has definite limitations.

The Canal

Surgery of the canal requires judgment regarding the margin of excision and some knowledge of temporal bone surgery, both to prevent stenosis and to preserve maximum hearing. Reconstruction beyond the bony canal should not be attempted unless the surgeon or a member of his team is prepared to do the full range of modern middle ear surgery, tympanoplasty, and indicated stapes or fenestration surgery. Facial nerve surgery must be anticipated but is not for discussion here.

Conclusions

Protruding Ears

Emphasis is placed on creating normal contour of the ear as seen in the lateral view, as well as correcting the protrusion. The otoplastic surgeon should attempt to duplicate natural appearance as nearly as possible. The technique developed is directed towards these goals. Postoperatively, the gradual convexity of the superior crus, without visible incision lines or angulations, is desired. The antihelix proper is subtly prominent and there is a definite groove between the antihelix and helix.

The general physician and the pediatrician are encouraged to be aware of this readily correctible deformity and recommend the procedure, especially where it seems important in the particular individual for his overall well being and outlook.

Reconstructive Procedures

Reconstruction of the external ear requires the incorporation of all plastic surgery principles, particularly in the use of both implants and grafts. Combined skin grafts utilizing a variety of both free grafts and grafts bearing their own blood supply must be in the armamentarium. Wherever possible, autogenous implant material is advocated.

In carcinoma, radical excision is essential. For carcinoma of the ear, remove underlying cartilage and bone. If the lesion escapes to the middle ear or mastoid bone, the prognosis is most guarded. If there is any question regarding the margin about the lesion, no principles of cancer surgery should be violated and reconstructive procedures should be disregarded. In most instances, however, some form of primary reconstruction is possible and desirable.

O Thou, who know'st the wants of human kind,
Vouchsafe me health of body, health of mind;
A soul prepared to meet the frowns of fate
And look undaunted on a future state;
That reckons death a blessing, yet can bear
Existence nobly, with its weight and care.

— Juvenal (60-140)

Tandearil®

oxyphenbutazone

Therapeutic Effects: Tandearil is a nonhormonal compound which may rapidly resolve inflammation and help restore normal joint function. Its action does not affect pituitary-adrenal function or impair immune responses. Its value in osteoarthritis is especially noteworthy because this disorder responds inconsistently to steroids and is often resistant to salicylates. Further, indomethacin is limited only to osteoarthritis of the hip, whereas oxyphenbutazone is effective in all forms of the disease.

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonamides, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should be closely supervised and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage. Make regular blood counts. Discontinue the drug and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, or a generalized allergic reaction may occur and require withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Osteoarthritis: The initial daily dosage in adults is 300-600 mg. in divided daily doses. When improvement occurs, dosage should be decreased to the minimum effective level; this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

For complete details, please refer to full prescribing information. 6562-VI(B)R

Availability: Tablets of 100 mg.

Chronic Nasal Dysfunction

FRANCIS L. LEDERER, M.D.*
Chicago, Illinois

A SLANG EXPRESSION, "Plain as the nose on one's face," dates back to the year 1660. This still holds over three centuries later as the story of the nose in health and in disease begins to unfold. The nose is the gateway to life and death (Holden) and while in many languages, including Hebraic, the words for "breath" and "soul" are practically identical, a more modern version would be to say that the nose is indeed State and Madison Streets of the respiratory tract. From an anthropomorphologic point of view the nose-form frequently identifies ethnic origin, tribal custom, as well as the happy hunting ground of physiognomists. Modern man's involvement in high speed driving, the manly art of self-defense, and other body contact sports frequently produce the battered nose syndrome, altering both appearance and function.

As originally blueprinted by the Master Architect, the contour and the composition of the framework of the nasal pyramid, as well as the design, content and type of lining of the cavity, were calculated to meet the needs of man. The external supporting structure serves to maintain and protect the airway to insure the primary function of respiration in warming, moistening and cleansing of air, as well as the secondary functions of olfaction, phonation (resonating chamber), gustation,** temperature adjustment, absorption as a therapeutic pathway, drainage and bacteriostasis. It may come as a surprise to some that the sense of smell is comparatively unimportant clinically and is rudimentary in man, yet the sensitivity is startling. The many environments man elects to live in have brought into play the importance of the nose as a humidifier, 1000 cc. of water being evaporated every twenty-four hours. This varies inversely with the humidity outside: when hot and humid, there is but little evaporation

*Otolaryngology specialist.

**See Test Your Word Score Page 1023.

from the nasal mucosa; when dry, there is considerable.

Normal nasal function depends upon six basic requirements:

1. Large surface area, including turbinates.
2. Moist surface (mucus sheath).
3. Movement and replenishment of mucus by cilia and glands.
4. Heat supply, in which the cavernous spaces are neither contracted nor engorged.
5. Proper biochemical composition of secretion, about a pH of 6.5.
6. Normal pathway for aeration.

When there is an absence of normal function as a basis for dysfunction, it could be represented either by hyper- or hypofunction as compared in the following tabulation which gives some indication of the wide variety of intrinsic and extrinsic factors which must be considered.

Nasal Function		
Normal	Hyper-	Hypo-
Anthropomorphic	Irritative	Abnormality
Respiration	a) Temporary	a) Developmental
Humidification	b) Prolonged	b) Acquired
Olfaction	Allergic	Medication
Ventilation	Medication	Febrile states
Drainage	Foods	Constitutional or
Filtration	Carbohydrates	systemic disorders
Ciliary action	Starches	Endocrine
Phonation	Climatic	imbalance
Gustation	Environmental	Psychogenic
Bacteriostasis	Infectious	
Barometer of emotions	Endocrine imbalance	
	Psychogenic	

No approach to a proper diagnosis of cause and effect will ever be superseded by the thoroughness inherent in a good history, a competently carried out physical examination, including anterior and posterior rhinoscopy, supplemented by laboratory aids when indicated by the findings. In accordance with an old aphorism, "Seeing is believing but feeling is the naked truth," probing and palpation with applicator and canula are important to correct diagnosis as well as treatment. To the experienced clinician the color, texture and contour of mucous membrane constitute valuable signs. The presence of secretion, whether watery, mucoid, suppurative, hemorrhagic or crusted, may

likewise figure prominently in arriving at a diagnosis of nasal dysfunction.

The abundant vascular supply of the nose and the relative accessibility of vessels, including *epistaxis digitorum* and *epistaxis feminis*, identify nosebleed as a most frequent dysfunction, represented as a primary or reflecting an underlying pathophysiologic phenomenon. Specific disease entities, including cardiovascular abnormalities, febrile states, exanthem, collagen aberrations, hematopoietic disturbances and hereditary multiple angiomas are occasionally associated with pulmonary arteriovenous phenomena.

Not only is the richness of the nerve supply of the nose the site of origin and the recipient of numerous reflex arcs but it also responds to fear, exaltation (the barometer of our emotions), as well as many modern vasoconstrictor and decongestant agents introduced into the nose and the anti-hypertensive *Rauwolfia* drugs popularly prescribed for oral administration. A boggy, wet, pale white mucosa may relentlessly block the nose until the pharmacologic relationship is discovered. It is of interest to note that the bouts of migrainous neuralgia are accompanied by a unilateral red eye, the production of tears and nasal stuffiness. The innumerable other causes of nasal dysfunction, particularly those producing nasal obstruction, are summarized as follows:

I Extranasal

A. Congenital Defects

1. Narrow bone bridge
2. Atresia of nares
3. Thick columella
4. Collapsed alae
5. Depressed tip
6. Dilated alae

B. Acquired Defects

1. Depressed fracture
2. Displaced cartilages
3. Atresia of nares
4. Neoplasms

II Intranasal

A. Congenital

1. Nasal septum
2. Lateral walls
3. Posterior choanal

B. Acquired

1. Nasal septum
 - a) Hematoma
 - b) Abscess
 - c) Deviations

2. Nasal cavity
 - a) Infection
 1. Acute
 2. Chronic
 3. Specific
 - b) Foreign bodies
 - c) Rhinoliths
 - d) Adhesions and synechia
 3. Lateral Nasal Wall
 - a) Simple rhinitis
 - b) Hypertrophic
 - c) Atrophic
 - d) Vasomotor
 - e) Hyperplastic
 - f) Purulent
 - g) Neoplastic
 - h) Specific
 4. Floor of nose
 - a) Cysts
 1. Nasoalveolar
 2. Nasolabial
- III Nasopharynx
- A. Adenoids
 - B. Neoplasms
 1. Local origin
 - a) Benign
 - b) Malignant
 - c) Specific
 2. By extension
 - a) Choanal polyp
 - b) Nasopharyngeal fibroma
 - c) Malignant tumor

At this point of the discussion it becomes apparent that chronic nasal dysfunction may be many things in many people. The

need to bear them all in mind is obvious but not necessarily to oversimplify the problem or to focus attention on the nose as the prime diagnostic target. While the blotchy mucosal pallor of vasomotor rhinitis, as more or less a subclinical type of allergy, constitutes the most frequently encountered cause of nasal blockage, offending allergens in themselves may be a considerable source of dysfunction. On a similar basis, the sneeze, the secretion, the anosmia and the obstruction may be associated with hyperplastic mucosal changes of varying degrees. The presence of polyps may reflect similar degenerative changes in any or all of the nasal accessory sinuses, at times as one part of the interesting triad of situs inversus and bronchiectasis or another disease combated with difficulty, viz., cystic fibrosis. When polyps are unilateral, neoplasia, such as inverted papilloma, or even malignant change must be ruled out by the careful histological study of all tissue removed. To end this discussion of a unilateral nasal blockage on a less sombre note, it may be that a foreign body or even a rhinolith may produce sizeable granulomas to confound the experts.

Medical Eponyms from England

In the first half of the nineteenth century, English physicians gave their names to various diseased conditions: Joseph Hodgson described dilatation of the aortic arch (Hodgson's disease, 1815); James Parkinson, paralysis agitans or shaking palsy (Parkinson's disease, 1817); Richard Bright, nephritis, or disease of the kidneys usually associated with dropsy and albumin in the urine (Bright's disease, 1827); Charles Bell, peripheral paralysis of the facial nerve (Bell's palsy, 1829); Thomas Hodgkin, malignant lymphoma, or involvement of the lymph nodes with enlargement of the spleen (Hodgkin's disease, 1832); Thomas Addison, pernicious anemia (Addison's anemia, 1849), and disease of suprarenal capsules (Addison's disease, 1849) — an early landmark in the coming science of the ductless glands.*

|| Epistaxis*

WILLIAM H. SAUNDERS, M.D.**
Columbus, Ohio

TRAUMA SHOULD be considered as the factor common to most cases of nosebleed. Anteriorly, the injury may be quite obvious, such as the trauma inflicted by picking the nose, or it may be more occult as when caused by excessive drying of the mucosa. Blowing of the nose may tear crusts from the mucosa and thus open blood vessels. Frequently the margins of a septal perforation crust and bleed.

Posteriorly, this sort of external trauma is not likely to occur. Instead, epistaxis frequently results from splitting of a sclerotic vessel caused by infection of the mucosa or hypertension. Often there is no obvious cause.

Common Errors and Misconceptions

Before describing the correct methods of diagnosing and treating nosebleed, there are several common errors or misconceptions that deserve emphasis.

Bilateral Bleeding

Rarely do patients bleed from both sides of the nose simultaneously. If blood comes from both sides, it is because it passes behind the nasal septum from one side to the other. Patients with blood dyscrasias or with severe facial fractures may bleed from both sides; others should not be expected to do so.

Arterial Ligation

Ligation of the external carotid artery for epistaxis is rarely indicated. It must be remembered that not all of the nasal blood supply is derived from the external carotid artery; bleeding may come from branches of the internal carotid artery. In these cases, the ethmoidal vessels may be ligated. Again, such a procedure is rarely required. Nevertheless, many carotid ligations have

*See Test Your Word Score Page 1028.

**Department of Otolaryngology, The Ohio State University, University Hospital.

been done to control epistaxis. *In most instances, more efficient packing would have served better.*

Pharmaceutic Preparations — Their Misuse

When nasal packing is improperly placed and the patient continues to bleed, doctors sometimes prescribe a drug supposed to control bleeding. Except in rare instances in which the patient is bleeding because of an actual deficiency of vitamin C or vitamin K, such preparations have no value.

Use of drug therapy in treatment of nosebleeds is often harmful because it causes the physician to rely upon a medical treatment for a surgical condition. The doctor administers drug therapy instead of removing poorly placed packing and repacking accurately at the bleeding site. Many drugs have been recommended and used in the treatment of ordinary nosebleed. Instances in which use of these drugs seemed effective should be reevaluated. It must be remembered that time is a factor in nosebleeds. Given enough time (whether or not these products are being used) most nosebleeds will stop spontaneously.

The best parenteral therapy for the patient with ordinary epistaxis is a narcotic like morphine or a sedative like seconal. The best pharmaceutic agents for topical use are adrenalin and chemical cauterants.

Death from Nosebleed

I have never seen a patient die because of nosebleed although I have treated at least three patients each of whom during their lifetime bled enough to require over 2000 blood transfusions. Patients become deathly pale and they faint, but they do not die. (Some authorities have reported death from coronary insufficiency secondary to severe nosebleed, but such instances must be extremely unusual.) When a patient bleeds enough to go into shock, his blood pressure falls and his bleeding is reduced to a trickle or it stops. Thus there tends to be a check on the amount of blood a patient can lose from epistaxis at any one time.

Conditions Not Causing Nosebleed

It is almost as important to emphasize conditions that are not the cause of nosebleeds, except rarely, as to emphasize those that are. Physicians who are not adept at intranasal packing and cautery often attribute nosebleeds to a disturbance in the blood clotting mechanism. A physician may pack the nose of a patient but not place the packing accurately; the bleeding then continues. Instead of replacing the packing the doctor mistakenly assigns the cause of bleeding to a supposed (but rarely present) hematologic disturbance. Alterations in the vitamin K or vitamin C blood levels, or changes in the prothrombin time, bleeding time, or clotting time, are not commonly the causes of epistaxis. When epistaxis is due to systemic causes such as scurvy, leukemia, or a change in the blood prothrombin level, the patient bleeds from various mucous membranes and into the skin and viscera. Why should a patient with a generalized hematologic disturbance bleed only from the nasal mucosa? The answer is that he doesn't or does so only very rarely, and then soon bleeds from another site. Nosebleed in a patient who is not bleeding from any other part of the body is almost always the result of local trauma.

Treatment

Most physicians at one time or another have had to treat a patient with nosebleed. Otolaryngologists may have this as a daily or weekly experience. There are different approaches, but each is arrived at by first identifying the exact bleeding site and, second, by stopping the bleeding by using cautery or by placing packing accurately.

The nose usually bleeds from one of three sites: (1) anteriorly at Kiesselbach's plexus on the septum, (2) from far posteriorly under the inferior turbinate, (3) from posteriorly and high in the nose (from the anterior ethmoidal artery). It is very important that the physician determine from which area his patient is bleeding because the treatment of anterior bleeding, which is simple, differs entirely from the treatment

Figure 1(a)

Figure 1(b)

Figure 1(d)

Figure 1(c)

Figure 1(e)

Fig. 1 — Treatment of nosebleeds from the anterior part of the nose. (a) First step — sucking clots and blood from the nose. Note gowns on both the patient and the doctor. (b) Second step — application of epinephrine to a cotton ball. (c) Third step—compression of the cotton for several minutes against the bleeding septum. (d) Fourth step — cautery of the bleeding vessel with a silver nitrate stick. (e) Same as (d) but using an electric cautery instead of silver nitrate.*

Fig. 2 — a, Three strings are needed. b, Packs can be made from roller bandage or gauze, but care must be taken that they are not too large or they will not only obstruct both choanae but also block the eustachian tube. This pack should also have a third string to dangle in the nasopharynx to make removal easier. c, Construction of a postnasal pack from a vaginal tampon.*

of posterior nosebleed. The treatment of the two different posterior nosebleeds also differs.

Anterior Nosebleed

All that is needed to control this bleeding is a bright light to help identify the bleeding spot, suction to clear the nose of blood and clots, and some form of cautery. Aqueous adrenalin, 1-1000, applied to cotton and inserted into the bleeding side (with pressure on the ala) will help control the bleeding until the doctor can perform cautery.

Figure 1 demonstrates the exact steps in identifying and controlling an anterior nosebleed. Note that the patient and doctor are gowned (a "must" in dealing with epistaxis); note also the use of chemical or electrical cautery. In the case of chemical cautery (usually a silver nitrate stick) local topical anesthesia is sufficient — cocaine 5 percent or pontocaine 2 percent is effective. For electrical cautery, injection of the mucous membrane with 1 percent xylocaine is advisable.

Fig. 3 — Postnasal packing. a, (left) First step. b, (right) Second step. Anterior packing with 1/2-inch petrolatum gauze is then placed. In addition to petrolatum it is well to lubricate all packing with an antibiotic ointment to prevent infection and odor.*

*From DeWeese, David H., and Saunders, William H.: *Textbook of Otolaryngology*, Ed. 2, St. Louis, 1964, The C. V. Mosby Co.

No packing is required after cautery of an anterior bleeding site.

The anterior ethmoidal artery bleeds from high and posteriorly in the nose and it can bleed briskly. To identify the exact bleeding site one needs a brilliant light (preferably a head mirror reflecting light from a 150-watt clear bulb) and a sucker to clear blood. By advancing the sucker tip further and further into the nose one comes to a spot where suddenly no blood appears. This indicates that the blood is going directly into the tip of the sucker.

With the exact spot of bleeding identified, a compressed cotton ball about as big as a bean, impregnated with vaseline or terramycin ointment, is pressed hard into the space between the septum and the middle turbinate (the superior meatus). This small pack should stop the bleeding, but to hold it securely additional packing of the superior meatus with one-fourth inch gauze stripping, again well greased, is advisable. Four or five days later, if bleeding has been checked, the packs are removed.

Posterior Nosebleed

Often occurring in older persons, these nosebleeds may come from the very back of the nose and usually from under the inferior turbinate. They are difficult for both patient and doctor. First, the bleeding from here is profuse and second, it is very difficult to work adroitly in the posterior nose where visualization may be difficult even in a patient without a nosebleed. Spot cautery is not possible in most instances and one must resort to the postnasal pack to control bleeding.

Figure 2 shows different types of postnasal packs. The essentials are that the pack not be too large — it need fit only one posterior choana and should not obstruct the eustachian tube; that the pack have strings attached anteriorly and posteriorly and be well greased.

Greasing with terramycin is recommended because packs greased in this way have no odor when removed and lack of odor implies lack of infection.

The postnasal pack must be seated *very*

firmly by strong traction on the two stout anterior strings (Figure 3). Then the anterior part of the nose is carefully and firmly packed with gauze stripping which again is greased with antibiotic ointment. Packing is removed in two or three days and replaced if there is recurrent bleeding. Patients requiring a postnasal pack should be in the hospital.

Blood Transfusions

If a patient is in shock due to blood loss, immediate transfusion may be required. Often, however, paleness and faintness are due not to blood loss but to the discomfort associated with placement of a postnasal pack.

There is a false sense of security that comes from checking the hemoglobin imme-

Fig. 4 — a (top) Severe nasal crusting like this is common in patients with hereditary hemorrhagic telangiectasia. Note also telangiectasia on lips, fingertips, and face — all common sites. b, (bottom) Septal dermoplasty operation. The skin grafts can be considered posterior extensions of the normal vestibular skin.*

*From Saunders, W. H.: Hereditary Hemorrhagic Telangiectasia: Its Familial Patterns, Clinical Characteristics, and Surgical Treatment. Arch Otolaryng 76:245, 1962.

diately after a severe nosebleed. The hemoglobin concentration which has occurred gives relatively normal values for hemoglobin, whereas the next day, after hemodilution has occurred, the patient's hemoglobin determination indicates severe anemia.

Hereditary Hemorrhagic Telangiectasia and Nosebleeds

The severe, repeated, life-long nosebleeds that mark hereditary hemorrhagic telangiectasia (Rendu-Osler-Weber disease) are known to most otolaryngologists. Nosebleeds which usually begin about puberty become worse as the patient grows older. A hemoglobin determination of four grams is not infrequent. Some patients with this disorder also bleed from the gastrointestinal tract and, in fact, hemorrhage has been reported from virtually every body orifice and into most organs.

This special type of nosebleed can now be controlled effectively by a surgical procedure called septal dermoplasty (Figure 4). In this operation the principle is to replace the

fragile epithelium in the anterior one-third of the nose by a split-thickness graft of skin from the thigh. The skin graft, being tough, resists trauma and prevents bleeding. Results in over 100 patients demonstrate that the procedure is effective. Some patients never bleed again, while others, who do bleed occasionally, do so much less severely and less often.

Another treatment for patients with bleeding from hereditary hemorrhagic telangiectasia is the use of ethinyl estradiol. This drug, given in a dosage of 0.25 mgm. daily, is said to convert the respiratory epithelium into a squamous epithelium. Thus it attempts to do medically what septal dermoplasty does surgically. Side effects of loss of libido and hypertrophy of the male breast may be serious. The medication must be used lifelong.

Patients who suffer seriously from nosebleeds caused by hereditary hemorrhagic telangiectasia should first have a septal dermoplasty. For those who need further help because of persistent bleeding a trial on estradiol is in order.

Hernia on the Frontier

Range doctors dealt frequently with hernias. Oregon doctor, J. R. Jonson, was called on a case of strangulated hernia. The sick man writhed in agony, and his abdominal muscles were so tense the doctor could not do a thing. He had no drugs with him and was as helpless as the crowd of sympathetic bystanders who had gathered around. One man squirted a stream of tobacco juice toward a spittoon.

"Bite off another chew," said the doctor.

When the man did, Dr. Jonson took the tobacco and inserted it into the patient's rectum. The nicotine quickly brought on a cold sweat and nausea. Muscles relaxed, and the doctor was able to reduce the hernia.

Richard Dunlop, M.D.: *Doctors of the American Frontier*

Ladder of Hermes

The Ladder of Hermes was a preparation contrived by Gilbert of England in the thirteenth century. It consisted of 60 simples, compounded by arithmetic progression into one all-purpose prescription: One ounce each of four simples plus two ounces each of four more simples plus three ounces each of four more, etc., until all 60 were incorporated into the final product.

This 15-step Ladder of Hermes was reputed to possess phenomenal potency in curing more than just 15 diseases!

Chronic Sinus and Broncho- Pulmonary Diseases

The Relationship

F. W. DAVISON, M.D.*
Danville, Pennsylvania

NUMEROUS MEDICAL articles of 20 to 30 years ago discussed the relationship between chronic sinus diseases and various types of chronic bronchopulmonary disease. Some pointed out that the chronic sinus disease was primary and the bronchopulmonary disease secondary.

Other authors thought that the pulmonary disease was primary and the sinus disease secondary. To substantiate this claim they cited the fact that cough and expectoration are not socially acceptable, so that in order to get rid of secretion the person with bronchiectasis would cough tracheobronchial exudate into the nasopharynx and then blow it into a handkerchief.

Investigations

Most authors, however, felt that the sinus disease was primary. To substantiate this claim animal experiments were done in which India ink was injected into the cavity of the maxillary sinus and was demonstrated in the lymphatics and also in the pulmonary tissues. This experiment was thought to establish that the mode of extension of the infection was by way of the lymphatics. Subsequent investigators showed rather more conclusively that in the first experiments large amounts of India ink were used, some of which overflowed into the nose and nasopharynx and was aspirated into the tracheobronchial tree.

They further demonstrated that the lymphatic drainage of the sinuses is into the retropharyngeal lymph nodes. Other investigators placed iodized oil in the nose while patients were asleep and later demonstrated its presence in the tracheobronchial tree by roentgen examination. Therefore this possible mode of extension of infection is apparently well established.

*Senior Consultant, Department of Otolaryngology and Broncho-Esophagology, The Geisinger Medical Center, Danville, Pennsylvania.

Aspiration of infectious material can undeniably initiate a bronchopulmonary infection. That this sequence of events is not inevitable is demonstrated by the large number of people who have chronic suppurative sinus infection of many years' duration but do not have any bronchopulmonary disease or symptoms.

Upper and Lower Respiratory Tracts

Something that needs re-emphasis is the fact that the upper and lower respiratory tracts are one physiologic unit and that mucosal misbehavior in both areas often has a systemic cause predisposing to disease in *both* areas.

Some of the systemic or constitutional diseases which predispose to infection in both upper and lower respiratory tracts are allergy, the antibody deficiency syndromes, cystic fibrosis, endocrine disturbances, especially poor adrenocortical function, malnutrition and other chronic debilitating diseases.

Rhinosinusitis and Bronchiectasis

One of the more frequently noted associations is the coexistence of chronic hyperplastic rhinosinusitis and bronchiectasis. In 1944 I wrote a paper entitled "Does Chronic Sinusitis Cause Bronchiectasis?" My conclusions were as follows: (1) chronic sinusitis and bronchiectasis frequently coexist, but one does not cause the other; (2) all patients in this series who had both bronchiectasis and sinusitis were of the hypersensitive type; (3) the allergic or hypersensitive state was an etiologic factor in 80 per cent of this series of 50 cases of bronchiectasis; (4) seventy-two per cent of the 50 patients developed bronchiectasis during the first decade of life; (5) seventy-four per cent traced the onset of their chronic cough to an acute bronchopulmonary infection; (6) mucosal edema was probably the chief factor responsible for the atelectasis which led to the development of bronchiectasis; (7) our results in the prevention and treatment of bronchiectasis will be improved when we know more about hypersensitivity and how to control it.

Administration of antibiotics to kill the germs and of corticosteroids to reduce the mucosal edema have greatly improved the results of treatment of these patients.

Thirty years ago in an effort to determine the inter-relationship between sinus disease and bronchopulmonary disease I analyzed the charts of 100 patients whose chief symptoms were chronic cough, chronic nasal discharge or bronchial asthma. Only those cases were included in this study in which sinusitis was possibly a factor.

In addition to the usual history and physical examination all patients had roentgen study of the sinuses and lungs. Bronchoscopic examination and bronchograms were made when necessary to clarify the diagnosis.

This study resulted in the following classification.

Classification of Chronic Non-Tuberculous Respiratory Disease

In Non-Allergic Individuals. (45 cases)

1. Suppurative sinusitis of nasal origin. (13 cases)
2. Suppurative sinusitis of dental origin. (9 cases)
3. Suppurative sinusitis. Suppurative bronchitis. (2 cases)
4. Suppurative sinusitis. Bronchiectasis. (14 cases)
5. No sinusitis. Bronchiectasis. (7 cases)

In Allergic Individuals. (55 cases)

1. Suppurative sinusitis. No bronchitis. Asthmatic symptoms. (9 cases)
2. Suppurative sinusitis. Suppurative bronchitis. Asthmatic symptoms. (17 cases)
3. Suppurative sinusitis. No bronchitis. No asthmatic symptoms. (7 cases)
4. Hyperplastic sinusitis. No bronchitis. Asthmatic symptoms. (8 cases)
5. No sinusitis. Suppurative bronchitis. Asthmatic symptoms. (7 cases)
6. No sinusitis. Nonsuppurative bronchitis. Asthmatic cough. (7 cases)

It is evident from this survey that different combinations of disease states occur. I think this classification is still valid. The

present day availability of antibiotics and corticosteroids has tremendously improved our therapeutic results. Prompt administration of these two agents will rapidly control the *acute* infections that formerly resulted in chronic sinusitis or bronchiectasis or both.

Treatment

Sinus disease should be treated on its own merits medically and/or surgically according to the judgement of the otolaryngologists. Many of the patients with bronchopulmonary symptoms were benefited by sinus surgery, but the results were not predictable. To achieve maximum benefit for the patient it is necessary to consider systemic defects such as allergy, metabolic disorders and immunologic deficiencies which sometimes contribute to perpetuation of the disease in both areas.

When considering the relationship of sinus infection to bronchial asthma I had the concept that if we treated the sinus infection by antibiotics or by surgery we were eliminating the bacterial protein, the antigen which could trigger an allergic reaction in a sensitized bronchial mucosa.

Nasopulmonary Reflex

Bray describes a mechanism which gives another possible explanation for the improvement we sometimes see in asthmatics following sinus surgery. He quotes Adam in picturing the asthmagenic area of the nose which begins with the lower margin of the middle turbinate and includes all of the upper air passage extending from this margin to the cribriform plate, both the lateral and septal surfaces of the nose being included. Sensory impressions gathered from this area pass through the sensory portion of the trigeminal and down the descending root of the trigeminal nerve to end at about the cells of the nucleus ambiguus, which represents the motor root of the vagus and glossopharyngeal nerves. In brief, these connections explain how stimuli arising in the ethmoid region of the nose may lead to bronchospasm through this nasopulmonary reflex.

One way to demonstrate this reflex is by

mechanically stimulating the middle turbinate with a cotton-tipped probe. Usually this stimulus results in a cough rather than a sneeze.

Cystic Fibrosis

Another type of disorder which affects both the upper and lower respiratory tracts is cystic fibrosis, also known as mucoviscidosis, which affects the upper respiratory tract almost as frequently as the lower respiratory tract. Before the correct diagnosis was established, a great many of these cases had been treated for asthma, bronchiectasis, or severe allergy of the nose and sinuses.

Cystic fibrosis is recognized today as one of the more common chronic diseases of childhood and adolescence and represents the most serious lung problem among American children. It also accounts for the majority of pediatric patients with chronic nontuberculous pulmonary disease. This disease entity deserves wider recognition and study by otolaryngologists. A good source of information is the "Guide of Diagnosis and Management of Cystic Fibrosis," published by the National Cystic Fibrosis Research Foundation.

Sinusitis and Asthma

Chronic hyperplastic rhinosinusitis and bronchial asthma frequently coexist. In 1963 I reported the study of the case histories of 50 patients who had a *severe* degree of chronic hyperplastic rhinosinusitis treated surgically, who had been observed by me over a period of at least five years. After carefully reviewing the case histories of these 50 patients it was found that asthma was totally relieved or greatly benefited in 16 of the 21 asthmatic patients. However, it must be pointed out that these patients also received antibiotics and corticosteroids.

The treatment methods which stood out as being really useful were: (1) antibiotics in bactericidal doses; (2) surgery to remove tissues which had suffered irreversible damage and also to provide ventilation and drainage; (3) management of coexisting food or inhalant sensitivity; (4) oral administration of 5 to 10 mgm. of Prednisone

for a month following operation.

Conclusions

My conclusions were as follows: (1) hyperplastic sinusitis is a manifestation of bacterial allergy (delayed hypersensitivity); (2) complete surgical removal of diseased tissue is necessary in advanced cases; (3) a temporary or permanent subclinical adrenocortical insufficiency is a conditioning factor leading to the development of this type of disease; (4) patients with this disease have an inherited or acquired endocrine defect predisposing them to recurrence; (5) small maintenance doses of corticosteroids can prevent recurrence.

Antibody-Deficiency Syndromes

In the last five years the antibody-deficiency syndromes have come to be recognized as factors predisposing to frequently recurrent infections in both the upper and lower respiratory tracts. Children with both the congenital or acquired forms of hypogammaglobulinemia are especially susceptible to purulent sinusitis and pneumonia.

If untreated, many of these children acquire chronic progressive bronchiectasis and ultimately die of their pulmonary complications if they survive the innumerable acute infections. These children with low gamma-globulin levels are especially susceptible to

the pyogenic organisms, principally the ubiquitous staphylococci, pneumococci, streptococci and hemophilus influenzae.

The acute infections can usually be readily controlled with antimicrobial chemotherapy; but if treatment is delayed or neglected the bronchopneumonia, sometimes diagnosed as "whooping cough," causes sufficient tissue damage to result in bronchiectasis. This is especially likely to happen in children who also have the atopic constitution. It is easy enough to understand how this oversight can occur, because when the child is at home and the diagnosis of a contagious disease such as whooping cough is made, it is thought best not to take the patient to a hospital or other facility where a chest x-ray might be obtained.

In going over the case histories of a series of 50 patients who had bronchiectasis it was found that 30 attributed the onset of their chronic cough to pneumonia and three to whooping cough.

Summary

When chronic suppurative disease is present in both the upper and the lower respiratory tracts the physician should look for a systemic predisposing defect such as the atopic constitution, the antibody deficiency syndrome, cystic fibrosis or a metabolic or endocrine insufficiency.

Hippocrates on the Post-Hoc-Ergo-Propter-Hoc Fallacy

In convalescence from disease, as also in protracted diseases, many disturbances arise, some spontaneously, some also from things the patient happens to take. Now, suppose that on the day when such perturbations arise, any innovation chances to have been made, such as a bath or a walk having been taken, or something unusual eaten; I know that, even if these were all perfectly proper, yet the bulk of physicians, just like the laity, would nevertheless ascribe the cause to one of these things, being ignorant of the true cause, and obscuring what was probably the most useful thing that could have happened. This should not be: one ought to know the effects of a bath or toil engaged in, at the wrong time; the same mischief will never arise from both of them nor from repletion, nor from such and such a food.

It is the manner of hypochondriacs to change often their physician... for a physician who does not admit the reality of the disease cannot be supposed to take much pains to cure it. —William Cullen

Maxilloethmoidal Polyposis

A Dystrophy of the Retropharyngeal Lymphatic System

THE ETIOLOGY of this dystrophy of the intranasal and intrasinal structures is so confused that the writer will not attempt to add to the confusion except to state that many but not all of the patients suffering from this condition apparently have an inherent and inheritable allergic diathesis which may appear clinically with a variety of presenting symptoms which often include sequentially: hay fever, nasal and/or sinal polyposis and bronchial asthma.

Boies¹ stressed the importance of "prolonged allergic conditions and marked edema within the mucous membrane causing a prolapse of the tissue with the resulting characteristic grape-like masses producing annoying symptoms of nasal obstruction, pressure, and excess secretion." Thompson² observed that "nasal polypi chiefly occur between the ages of 20 and 30 and are said to be more common in men than in women. They are rarely found in the young. In 10,000 patients observed in ten years, only six cases were met with in children, the youngest being six and one-half years." Lacoarret³ observed that a malignant growth or meningocele may be concealed by or mistaken for a nasal polypus.

Increased Lymph Flow

During episodes of severe reaction to infectious or allergic stimuli, the physiopathologic basis for the formation of most of the polypi occurring in the maxilloethmoidal area is related to the proclivity of, and necessity for, the sinal mucosa and turbinal tissue to increase their volume and approximate the capacity of or completely obliterate the air-containing cavities of the nose and paranasal sinuses. The necessity for this functional pathology stems from the need for an

J. MATHEWS ROBISON, SR., M.D.*
Houston, Texas

increase in production of capillary filtrate, tissue fluid and volume of lymph flow during pathologic states so that a constantly changing pericellular environment may be maintained for the cells of these tissues.¹¹

Lymph Node Obstruction

A variation of this etiologic process is the lymphedema and/or polypoid protrusions of the mucosa formed due to blocking of the lymph flow through the retropharyngeal lymph nodes during malignancy and specific diseases such as glanders and diphtheria, the pathogens or toxins of which produce swelling and blocking of the lymph nodes. This latter type of intrasinal edema and intranasal turgescence is often preceded and accompanied by effusion into the tympanums which usually begins unilaterally and is frequently the chief complaint of the patient.^{12,16,23}

Defects

Premature involution and atrophy²¹ of the lymph nodes and/or congenital localized gross tortuosity of the lymph vessels have been described by Yoffey and Courtice²⁰ as the cause of congenital lymphedema and elephantiasis of the leg. A similar process may be the cause of unilateral polyposis which, if occurring in the young, may be intractable and not curable by insertion of balloons into the maxillary sinuses. However, in certain patients much can be accomplished by very frequent polypectomy.

During mild reactions such as those following temperature changes and/or transient irritation by bacteria and/or allergens, the nasal and sinal tissues may promote physiologically adequate lymph flow solely by swelling against their own inherent tissue pressure. However, during severe reactions to infection and/or allergic stimuli, these tissues may have to swell sufficiently to obliterate their air-containing cavities with an incompressible medium so that the pulsations of the dilated arterioles and arteriovenous anastomoses may be transmitted to the lymph vessels and increase lymph flow through the lymph nodes, thereby fa-

cilitating the processing and removal of the increase in products of cell metabolism, toxins, bacteria, particulate matter, viruses and proteins not used as food by cells of the part.¹¹

Pathophysiology

The sinal cavities are rudimentary at birth. During infancy and childhood the nasal and potential sinal cavities can be filled readily by swelling of their turbinal tissue and mucosa, and lymph in the absence of lymphatic obstruction is propelled easily through the comparatively numerous lymph channels and retropharyngeal lymph nodes where antibodies are formed as the body begins to develop its acquired immunity. As the sinuses develop air-containing cavities normally they are lined by mucosa which is "seldom more than .02 mm. in thickness"⁵ and is a nonabsorbing membrane because it has no interstitial spaces.⁴ When normal, the maxillary sinal mucosa probably possesses the least tissue pressure of any tissue of the body. This is evidenced by its tendency to become edematous during primary hypoproteinemia* due to albuminuria, as is seen so often in nephritis and/or malnutrition during childhood. This type of edematous sinal mucosa may be erroneously diagnosed by x-ray as sinusitis of bacterial origin.

The low tissue pressure of this mucosa aids in understanding the process of "taking cold" or cold allergy which is, quoting from Dorland,¹³ "a condition manifested by local and systemic reactions, mediated by histamine, which is released from mast cells and basophils as a result of exposure to cold." This concept of circulating histamine would portend that the sinal mucosa due to its low tissue pressure would be the first tissue to become edematous during "taking cold." The excess tissue fluid derived from this process, depending upon the nature and amount of its protein content, would stimulate a compensatory turgescence of the turbinates as they promote the flow of lymph from the sinuses.¹¹

During purulent infection, as this very thin mucosa becomes edematous and approximates the capacity of the sinus, it with the

*See Test Your Word Score Page 1028.

aid of its cilia forces the sinal secretion through the ostium. Following completion of this mechanical process there remains in the very edematous sinal mucosa a large amount of highly proteinized tissue fluid. If the physiology of the lymphatic system of this region is like that of most of the other parts of the body, the protein in this fluid will be returned to the veins after it has been processed while passing through at least one lymph node. Certain small protein molecules such as ptomaines, venoms and toxins may be absorbed directly by the veins without previous processing by the lymph nodes. The possibility of the nasal and sinal mucosa acting as an organ of excretion of its highly proteinized tissue fluid will be discussed in another sequence in this paper.

During allergic reactions, as histamine is released in the nasal and sinal mucosa, an increase in permeability of the capillaries occurs and there may be rapid effusion of filtrate which contains comparatively little protein. This type of effusion is exemplified by the quick swelling and rapid disappearance of the edema of hives and angioneurotic edema and is evidence confirming the low protein content of effusion due to purely allergic reactions. This rapid absorption is noted particularly when the time of absorption is compared with the prolonged swelling of the tissues following subcutaneous hemorrhage.

The foregoing description of some of the physiologic principles of the lymphatic system should be considered as being applicable to the general principles of the physiology of the lymphatics in most of the areas of the body. These principles are applicable to the nose and paranasal sinuses, but their adaption to these areas, particularly as they relate to the processes of capillary filtration of protein and lymph flow and immunity, is modified by developmental, anatomical and aging characteristics which set this area apart from the other areas of the body.

One of the most essential and important physiologic characteristics of the body is the ability of the blood capillaries to selectively filter into and remove from each part of the body only those components of the blood

which promote the special physiology and functional pathology of the part. Could the mucosa of the nose and paranasal sinuses with its specialized physiology also have a selective excretion function? This function of excretion could have a dystrophy which would cause retention within the interstitial spaces of the mucosa of tissue fluid containing proteins derived from the blood which, if they exist in a state of conglutination,¹⁵ might not be excretable through the mucosa. In proportion to their effective osmotic pressure these nonexcretable proteins hold the water component of the tissue fluid in the mucosa. Following recurrent episodes of increased capillary filtration due to infection and/or liberation of histamine during allergic reactions, the interstitial spaces of the mucosa become widely dilated and alternating areas of fibrosis, and dilated tissue spaces appear first in the sinal mucosa and later along the lymph channels in the middle meatus. Presence of this type of lymphedema for a protracted period of time may produce this type of dispersed areas of fibrosis in other areas of the nasal mucosa. During episodes of stress, as the tissue pressure rises in this type of mucosa, polypoid protrusions of the mucosa are formed from the areas of dilated tissue spaces.

Recognition of the sinal and/or the nasal mucosa as an organ of excretion is enhanced by the observation that normally the inside of the nose is practically sterile.² Thompson emphasizes the secretory functions of the nose when he states, "It has been estimated that in 24 hours over a liter of water is supplied by the nose and there are no arrangements in the mouth, pharynx or windpipe for secretion of any such quantity. The importance of these bacterial functions is realized by remembering that at least 10,000 litres of air pass through the nose in 24 hours and that at the lowest estimate 1,500 organisms are inhaled into the nose every hour." Also he emphasizes the necessity of "respecting the erectile tissue of the nose, as the ciliated epithelium, when once destroyed, is never renewed. It is better to be a partial mouth breather than to have free nasal passages with these protective mem-

branes seriously damaged."

Remington¹⁴ et al. recently published a significant contribution to knowledge of the defense mechanism of the nose which also is in accord with the writer's theory that the nasal and sinusal mucosa have as one of their necessary and vital physiologic and functionally pathologic proclivities, the excretion of protein, the quantities and types of which are related to the etiology and characteristics of the capillary filtrate and tissue fluid and the magnitude of the tissue pressure of the area occupied by the tissue fluid. Quoting the Summary of Remington et al.,¹⁴ "Serum proteins and antibody activities were found in nasal secretions of normal and allergic individuals. The serum proteins in highest concentration were gamma 1A globulins and albumin; gamma 2 globulins were present in all specimens, but in lower concentrations. Antibody activity to tetanus and diphtheria toxoids and streptococcal M. protein was found in nasal secretions of normal volunteers whose sera showed high titers to the same antigens. Reagenic antibody activity was demonstrated in the nasal secretion of allergic individuals, but not in those of non-allergic persons. The possible role of nasal secretions in host immunity and nasal allergy is discussed." This article by Remington et al. is worthy of attention by those interested in allergy and immunology, and their findings are in accord with the opinion of Drinker and Yoffey¹ concerning the lymph nodes as sites of antibody formation. The nodes may even be instrumental in the production of a general immunity. McMaster and Kidd⁸ (1937) suggested that "the immunity conferred by clinical Jennerian vaccination may be largely of lymph node origin."

Retropharyngeal Nodes

The lymph nodes as sites of antibody formation apparently is one of the most important considerations of the etiology, progressive development and ultimate morbidity of maxilloethmoidal polyposis. The intranasal and intrasinus structures, the adenoid, nasopharynx, eustachian tube and middle ear develop from the embryonic first

branchial pouch. The lymph from all of these structures flows into the pre-eustachian tubal lymphatic plexuses¹⁶ and then into the retropharyngeal lymph nodes. There is free communication between these plexuses across the nasopharyngeal surface of the soft palate. This free communication allows lymph from physiologic or pathologic processes on either side to flow into the retropharyngeal nodes of one or both sides. This anatomic development is responsible for the occurrence of otitis media with effusion in the contralateral ear due to unilateral infection and/or malignancy in the nose, paranasal sinuses and nasopharynx.^{11,12,13}

The retropharyngeal lymph nodes are present at birth but exist as islands of lymphocytes along the lymph pathways. As the necessity for production of antibodies occurs during childhood these islands develop into two chains of nodes.¹⁹ The relative frequency of occurrence during childhood of retropharyngeal abscess due to suppuration arising in a retropharyngeal node and the relative absence of this condition in the adult is some evidence of atrophy of these lymph nodes. The writer investigated the presence of these nodes in relation to otitis media with effusion. Under the supervision of Dr. Donald Duncan, head of the Department of Anatomy in the University of Texas Medical Branch, and his associates, sixty cadavers of adults were dissected by medical students with particular relation to the presence and location of the retropharyngeal lymph nodes. In one cadaver one node was found immediately under the eustachian tube; in four cadavers there were no lymph nodes discernible by gross inspection. This apparent atrophy of these nodes was reported in 1942 as one factor in the etiology of effusion in the middle ear due to lymphatic blockage of a semiatrophic lymphatic system.¹² The physiologic atrophy of these lymph nodes apparently occurs as a defense mechanism which reduces the probability of abscess occurring in the very vital regions of the base of the skull.²¹

The table of the relative amounts of protein present in the plasma and in polypi in patients having maxillary ethmoidal polypo-

sis reveals that the differential in the osmotic pressure between the fluid in the polypi and the plasma is of a magnitude which precludes fluid in the polypi being absorbed readily by the blood. This type of polyposis nasi, like the solitary choanal polypus, usually has its beginning as a generalized or localized edema of the nasal mucosa long before polypi appear in the nasal cavities. As the edema of the mucosa increases, there is a loss of the inherent contractility and tissue pressure of the mucosa, as stagnant tissue fluid accumulates and dilates the tissue spaces.

Tissue pressure is related to the following variables taken in part from Drinker and Yoffey^{4,11,20}:

1. According to its magnitude tissue pressure resists capillary filtration and promotes capillary absorption and lymph flow.

2. Tissue pressure is gauged by the resistance tissue offers to dilation of its interstitial spaces by edema fluid.

3. Tissue pressure is proportional to the density and elasticity of tissue and decreases as the tissue loses its elasticity.

4. The integument encompassing the skin and bone, also facial places resist an in-

This table records the relative values of the protein content derived by electrophoresis, and also the colloid osmotic pressure of the plasma and tissue fluid of patients with maxilloethmoidal polyposis. The values of colloidal osmotic pressure were found through the use of the nomogram of Wells, H. S., Youmans, J. B., and Miller, D. G., Jr. (J Clin Invest 12:1103, 1933).

crease in tissue pressure (walls of sinuses and walls of the nasal cavities).

5. Tissue pressure increases with the rate of dilation of the interstitial spaces and increases as these spaces become filled with fibroblasts.

6. Tissue pressure may be increased by application of physical pressure to the surface of the part.

Treatment

A very effective method of increasing the tissue pressure of the sinusal mucosa and reversing or retarding the progress of the pathology is to insert into the maxillary sinus an artificial polypus in the form of a balloon and to fill the balloon with iodized oil. As oil is added to the balloon it expands and increases the tissue pressure of the mucosa and promotes absorption of the edema fluids.²²

As this is accomplished, the weight of the heavy iodized oil displaces the sinusal secretion. By obliterating the sinusal cavity with an incompressible medium, the pulsations of the arterioles and dilated arteriovenous anastomoses are transmitted to the lymph vessels. This transmission produces absorption of the edema fluid and increases the flow of lymph-bringing agents from the blood (hormones?) which may neutralize the conglutinant^{9,15} in the tissue fluid and either allow the excretion into the nasal cavities of the proteins in the edema fluid or facilitate their passage through the semi-atrophic lymphatic system. McMaster has reported that pulsatile pressure produces an increase in lymph flow seven times greater than constant pressure even though the systole pressure was never greater than the constant pressure.^{8,9,10}

Indications

The indications for insertion of balloons into the maxillary sinuses are principally related to pathologic processes which cause retention of an excessive amount of tissue fluid in the mucosa of one or both of the maxillary sinuses. The capacity of the maxillary sinuses often equals the sum of the capacities of all of the other sinuses. Treatment directed only to the maxillary sinuses

often reduces the intranasal turgescence and promotes resolution of pathology in the other sinuses. This principle may be applicable to both allergic and purulent sinusitis or allergic sinusitis with secondary infection.

Bronchial asthma associated with maxillary sinusitis may often be relieved by insertion of balloons into the maxillary sinuses. This type of treatment has also been successful in helping to cure subacute and chronic purulent sinusitis, incipient bronchiectasis, perennial allergic rhinitis and certain types of otitis media with effusion which are associated with unilateral or bilateral latent purulent sinusitis.

Contraindications

Contraindications to insertion of balloons are any type of acute allergic or purulent rhinitis or sinusitis or acute bronchial asthma. Before insertion, a high leucocytosis or eosinophilia should be brought under control with steroid hormones and/or antibiotics. If this is not done, insertion of balloons may precipitate Löffler's or Harkavy's syndrome.

X-ray of the chest and an electrocardiogram are indicated in patients with high blood eosinophilia and reduced pulmonary function.

The writer has inserted balloons into the sinuses of about 500 patients without any serious complications. Most of the writer's patients have had their balloons in their sinuses for about three months. However, quite a number of them have insisted that the balloons be left in their sinuses for from six to eight months to one year.

Balloons are not inserted during the patient's hay-fever season and should not be removed during that season. If they are, the patient may have a severe attack of asthma. As oil is added to the balloons about every two or three weeks, newly formed polypi may present in the middle meatus. These may be removed without the danger of precipitating an attack of asthma if balloons are in the sinuses and are well inflated. In 1895 Semon²⁴ reported asthma following polypectomy.

The technique of insertion of balloons can be found in the articles listed in the author's bibliography.

Many of the writer's patients have been treated for allergy for years before balloons have been inserted into their sinuses. Obviously the insertion of balloons would not be necessary if the treatment for allergy prevented or caused the polypi to disappear. If a patient continues to take injections from an allergist after balloons are inserted into the maxillary sinuses, frequently the dosage must be reduced. If it is not reduced, the patient may have an episode of bronchial asthma following each injection. The writer usually insists that the patient continue his treatment for allergy.

Summary

The physiology and functional pathology

of the lymphatic system has been described as it is related to maxilloethmoidal polyposis. A method of treatment of maxilloethmoidal polyposis has been described and its indications and contraindications given. The possibility of the nasal and sinusal mucosa being an organ of excretion during pathologic states has been suggested.

Note: Author is grateful to Franz Leidler, M.D. and his associates at the Memorial Baptist Hospital Laboratories for the electrophoresis of plasma and tissue fluids.

The balloons used were made by C. R. Bard, Inc., Murray Hill, New Jersey. The size used most frequently were those containing 8 mm. or 10 mm. deformable heads.

'Thorazine' is useful as a specific adjuvant in the above named conditions.

The following is a brief precautionary statement. Before prescribing, the physician should be familiar with the complete prescribing information in SK&F literature or *PDR*. **Contraindications:** Comatose states or the presence of large amounts of C.N.S. depressants. **Precautions:** Potentiation of C.N.S. depressants may occur (reduce dosage of C.N.S. depressants when used concomitantly). Antiemetic effect may mask other conditions. Possibility of drowsiness should be borne in mind for patients who drive cars, etc. In pregnancy, use only when necessary to the welfare of the patient. **Side Effects:** Occasionally transitory drowsiness; dry mouth; nasal congestion; constipation; amenorrhea; mild fever; hypotensive effects, sometimes severe with

I.M. administration; epinephrine effects may be reversed; dermatological reactions; parkinsonism-like symptoms on high dosage (in rare instances, may persist); weight gain; miosis; lactation and moderate breast engorgement (in females on high dosages); and less frequently cholestatic jaundice. Side effects occurring rarely include: mydriasis; agranulocytosis; skin pigmentation, lenticular and corneal deposits (after prolonged substantial dosages).

For a comprehensive presentation of 'Thorazine' prescribing information and side effects reported with phenothiazine derivatives, please refer to SK&F literature or *PDR*.

Management of Acute Suppurative Sinus Disease

FREDERICK T. HILL, M.D.*
Waterville, Maine

PRESENT DAY management of acute suppurative disease is conservative. The medical advances of the past few decades provide us with a better understanding of the disease processes and a more effective means of control. The diagnosis of acute sinusitis is not difficult if a careful history and examination is done.

Etiology

The role of allergy in preparing the stage for an acute infection is not completely understood, but many workers feel it is important. Also, many investigators feel that vitamin deficiencies, endocrine imbalances, poor environment, insufficient outdoor exercise, lack of proper humidity in artificially heated homes, prolonged exposure with chilling of the body surfaces, and fatigue may be predisposing factors. Anatomical defects such as adenoids, infected tonsils, or deviated septa are certainly important intrinsic factors, and any of these may provide suitable soil for subsequent bacterial invasion. Because of the cleaning action of the cilia the sinuses are sterile, even though bacteria may enter them. Anything that causes impairment of or absence of the cilia leads to a retention of bacteria and a predisposition to sinusitis.

Symptoms

Common symptoms generally are: malaise; tenderness over the involved sinus or pressure; headache worse in the morning and subsiding later in the day; nasal obstruction, a discharge, mucoid at the onset and becoming purulent later; and varying degrees of fever. Findings include nasal obstruction, uni- or bilateral, congested turbinates, and purulent or mucopurulent discharge. Roentgenograms and less often transillumination may confirm the diagnosis. Because of the possibility of an allergic factor, examination of the nasal secretions for eosinophiles is worthwhile.

*Head of Department of Otolaryngology, Thayer Hospital.

Treatment

In acute maxillary sinusitis, bed rest, promotion of drainage, sedation for pain, and indicated antibiotics based on culture and sensitivity studies, may be all that is needed; although, vasoconstrictor sprays and nasal suction, following the procedure of Proetz, can be very helpful. Patients who experience severe pain and have purulent discharge, or roentgenograms suggesting a delay in resolution, or inadequate drainage need additional treatment. In such cases, minor procedures such as infracture of the middle turbinate, turbinotomy of the anterior ends of the middle turbinates, or opening of the agger-nasi cell may be helpful in providing better drainage. If the x-ray shows a fluid level, puncture through the inferior meatal wall and irrigation of the maxillary sinuses are indicated. In persistent cases, however, it may be necessary to perform an intranasal antrostomy to provide sufficient drainage from the antrum.

Persistent acute maxillary sinusitis is an indication for intra-nasal antrostomy which may prevent the later formation of an antro-alveolar fistula. This procedure should be done through the lateral wall of the inferior meatus, by perforating the wall with a trocar and then enlarging it with biting forceps to get an opening of sufficient size. Care must be taken not to injure the orifice of the lacrimal duct, situated anteriorly, just under the overhanging inferior turbinate.

Acute frontal sinusitis is common in adults but rare in children. If frontal pain and tenderness over the sinus, edema of the upper eyelids, or clouding and fluid levels on x-ray persist, a trephine of the floor of the frontal sinus may be required. An incision should be made just inside the eyebrow on the mesial

side, the soft tissues elevated, and the sinus opened sufficiently to allow an insertion of a polyethylene tube. The tube should be left in place and daily irrigations of normal saline continued until the symptoms subside and the saline freely enters the nose.

While frontal sinusitis is rare in children, acute infections of the ethmoids and antra are at times encountered. Conservative measures usually are effective unless there has been a delay in seeking treatment, in which case the possibility of orbital abscess must be kept in mind. Acute suppurative sphenoiditis is rare and is usually an acute exacerbation of a chronic infection.

Orbital abscess, secondary to ethmoiditis, should be drained externally, using the conventional approach for the external ethmoidectomy operation. The orbital periosteum is elevated posteriorly and the orbit decompressed. This may require ligation of the anterior ethmoid artery, or it may be controlled by the use of a small metal clip such as used by the neurosurgeon. Occasionally, where there is marked swelling of the lids, secondary incisions through both the upper and the lower lids and the insertion of a rubber drain may be indicated.

Conclusions

Acute suppurative sinusitis usually responds to conservative management unless complicated by pre-existing factors or delays in obtaining treatment. The use of antibiotics, based upon culture and sensitivity studies, will eliminate most of the complications formerly encountered. Advantage should be taken to suggest correction of significant intrinsic or extrinsic factors aimed at the prevention of future attacks, and on occasion, special operative procedures are required to alleviate severe or persistent symptoms.

Evolution

The karygranulomes, not the idiogranulomes or microsomenstratum in the protoplasm of the spermatogonia, unite into the idiosphacrosome, acrosoma of Lenhossék, a protean phase, as the idiophacrosome differentiates into an idiocrytosome and an idiocalyptosome, both surrounded by the idiophacrotheca, the archoplasmic vesicle; but the ideoctosome disappears into the metamorphosis of the spermatid into a sphere, the idiophtharosome. — William Osler

Sensori- Neural Hearing Loss

Its Nature and Etiology

THEO. E. WALSH, M.D.*
St. Louis, Missouri

SENSORI-NEURAL HEARING loss may be either congenital or acquired. Congenital sensori-neural hearing loss may be on a developmental basis or may be the result of Rh incompatibility and kernicterus, maternal rubella in the first trimester of pregnancy, anoxia and viral infections.

Congenital sensori-neural hearing loss is usually bilateral and severe. It is noticed by the parents when the child is quite small and fails to respond in the usual way to loud sounds and also fails to acquire speech. The parents are greatly disturbed and need the physician's sympathetic attention. Although there is nothing medical that can be done for this type of hearing loss, training in speech, the use, by means of hearing aids, of any residual hearing that may be present, and special schooling are essential. The parents should be advised that these children frequently have a high I.Q. and with proper schooling will learn to communicate and become useful citizens. They should be in a special school early, ideally at the age of three years.

The acquired sensori-neural hearing loss may be the result of: (1) acoustic trauma, (2) degenerative changes, (3) head trauma, (4) heredity, (5) infections, (6) Meniere's disease, (7) ototoxic drugs, (8) tumors of the eighth nerve and (9) vascular accidents.

In the diagnosis of sensori-neural hearing loss the tuning fork is the most useful tool. If the patient hears better by air conduction than by bone conduction the hearing loss is sensori-neural. In the examination of such patients a pure-tone audiogram is a useful record of his hearing and establishes the threshold of his hearing at the various frequencies at which he is tested. He must be tested both by air and by bone conduction. A speech audiogram, i.e., a test of the patient's ability to hear and understand speech, is essential if we are to be able to advise

*Professor of Otolaryngology.

him whether he can be helped by hearing aids or other means. Although the average of the patient's threshold at the speech frequencies on the pure-tone audiogram is indicative of his speech reception threshold, the pure-tone audiogram tells us nothing of his ability to understand speech when it is delivered at a sufficient intensity above his threshold. In this test, a list of phonetically balanced monosyllabic words is presented to the patient at approximately 40 decibels above his speech reception threshold. His discrimination score is the percentage of words repeated correctly. In sensori-neural deafness the discrimination score is always markedly reduced.

Acoustic Trauma

Individual sensitivity to loud sounds varies considerably. Exposure to excessively loud noise as in industry (boilermakers, drop-forge workers, etc.) or to repeated insults, such as gunfire, leads at first to a temporary threshold shift. The patient exposed to such loud sounds complains first of a tinnitus and an inability to hear. If no further exposure is experienced the hearing may return to normal. Repeated exposure causes permanent damage. The pure-tone audiogram shows a loss at 4,000 cycles. As time goes on the loss may spread for both the high and the low tones but is usually most severe at the 4,000 cycle tone. Such loss is usually bilateral and progressive.

Degenerative Presbycusis*

The hearing loss of presbycusis occurs in the older age groups and is probably the most common type of acquired sensori-neural hearing loss with which we have to deal. In presbycusis the pure-tone audiogram shows a sharp drop in the high tones, usually 2,000 cycles and above, and is slowly progressive. In the earlier stages the speech reception threshold is not greatly impaired. The discrimination for speech, however, is greatly impaired. Such patients complain that they hear but do not understand. They are particularly bothered by ambient noise and hear and understand poorly in a noisy environment but fairly well when

speaking vis-a-vis in a quiet room. It is obvious that with a good speech reception threshold and poor discrimination a hearing aid would be useless. Whenever the speech reception threshold deteriorates to 40 decibels or worse, a hearing aid may be justified. The patient, however, should be instructed that it is difficult to become accustomed to this aid and that he will have to persevere in the use of it.

Head Trauma

A blow of the flat of the hand on an ear, an explosion near the ear, or sometimes an inexperienced dive when the ear hits flat against the water may cause a rupture of the tympanic membrane and give rise to a conductive deafness. At the same time great trauma is done to the cochlea by this excessive pressure and a sensori-neural deafness occurs. This may also happen with a blow on the side of the head, usually with a flat object. The hearing loss in such cases is sudden, usually unilateral, and may be total.

Heredity

Not infrequently one sees a patient with either a unilateral or a bilateral hearing loss of any severity who gives a history that the parent, grandparent and great-grandparent all acquired such a hearing loss at the same age. Total congenital hearing loss may be hereditary. Hereditary hearing loss manifesting itself in the teens is usually more in the high tones, spreads rapidly, and may become total.

Infections

Various degrees of sensori-neural deafness may be acquired after attacks of viral infections such as mumps, measles, flu, etc. The loss may be bilateral or unilateral, may be of any degree, and is not usually progressive.

Meniere's Disease

Although Meniere's disease is primarily a cochlear disease the patient usually presents himself complaining of acute vertiginous attacks. In obtaining a history of such an attack one can usually elicit the fact that it is accompanied by a roaring tinnitus in one ear, sensitivity to loud sounds and difficulty

*See Test Your Word Score Page 1028.

in hearing. The classical triad of Meniere's disease is therefore a roaring tinnitus, vertiginous attacks and sensori-neural deafness. In testing such patients we find in the early stages that the low tones are more affected as a rule than the high. The patient is peculiarly sensitive to loud sounds. The same tone applied to each ear will be heard differently in the two ears (diplacusis). Hearing in such cases fluctuates and during remissions may be perfectly normal. As time goes on, however, the hearing becomes gradually worse and finally is quite useless. Although in many cases the speech reception threshold is not greatly impaired, the discrimination score is always markedly poor. In the early stages, medical therapy may be of great value in preserving the hearing and controlling the vertiginous attacks. When, however, the hearing has deteriorated and does not fluctuate, medical therapy is of no avail. It is fortunate that Meniere's disease is more commonly unilateral than bilateral.

Ototoxic Drugs

The administration during infections of such drugs as dihydrostreptomycin, kanamycin, quinine, etc., has caused severe sensori-neural hearing loss. This is rapidly progressive with the antibiotics and may be total. Excessive use of aspirin may cause some temporary sensori-neural hearing loss; but

hearing usually improves when large doses of aspirin are discontinued.

Eighth Nerve Tumors

The hearing loss in tumors of the eighth nerve is slowly progressive. The patient usually complains early of a tinnitus and sometimes of an inability to understand speech, although he can frequently hear it. Tumors of the eighth nerve usually arise on the vestibular division of the nerve and affect the cochlear division by gradual, increasing pressure. Unless the tumor is recognized and removed early the loss may be total.

Vascular Accidents

Occasionally sudden loss of hearing is experienced in one ear. The explanation for such sudden total hearing loss is usually presumed to be a hemorrhage into the inner ear or some central nervous vascular accident.

Summary

Sensori-neural hearing loss may be congenital or acquired. Although with the possible exception of Meniere's disease medical therapy is of little avail in improving the hearing loss, the physician can serve a very useful purpose in advising those afflicted with sensori-neural deafness in the use of hearing aids, education, etc.

Green Medicinals Herbs for the Throat

Ecclesiasticus said: The Lord hath created medicines out of the earth and a wise man will not abhor them. Medicinal herbs for the throat include black currant leaves, columbine, hedge mustard, knapwood, quinsywort, rampion, throatwort, violets, and yellow dock, yielding gargles, syrups, and tonics.

A tempting ice can be prepared from the leaves and shoots of the black currant tree:

Black Currant Tree Ice

Take two or three handfuls of young black currant leaves and shoots and throw them into a saucepan with four cups of boiling water — add a pound of sugar and the juice of two lemons and mix well. Let it boil three times, then pass the mixture through a sieve and allow it to cool — when lukewarm add a tablespoon of gelatine and pour into a mould and freeze.

— C. F. Leyer: Green Medicine

There are 36,700* undetected diabetics in Minnesota

Most of these are probably among patients over 40; the overweight; relatives of diabetics, and mothers of large babies. By the time polyphagia, polyuria, polydipsia, pruritus or other overt symptoms of diabetes appear, damage may have been done that could have been minimized. DEXTROSTIX® gives you a reliable blood-glucose estimate in 60 seconds.

Why Wait?

*Based on Statistical Report, U.S. Dept. Commerce, ed. 86, and Fisher, G. F., and Vavra, H. M.: Pub. Health Rep. 80:961 (Nov.) 1965.

Note: DEXTROSTIX is not meant to replace the more precise analytical laboratory procedures such as needed in glucose tolerance testing.

Acoustic Tumors

Diagnosis and Management

WILLIAM F. HOUSE, M.D.*
WILLIAM E. HITSELBERGER, M.D.**
Los Angeles, California

FOR REASONS WHICH are not known, the acoustic nerve is the most common site of benign neuromas in the body. Acoustic tumors are believed to arise from the Schwann cells of the nerve sheath and are more properly called "Schwannomas."¹ Although they are benign and slow growing, their location when enlarged in the posterior fossa, next to the brain stem, makes them a serious death-dealing lesion.

The first successful removal of an acoustic neuroma was accomplished by Sir Charles Ballance in 1893.² To Harvey Cushing goes credit, however, for alerting the medical profession to the problem of acoustic tumors and for standardizing the surgical approaches to these lesions. The monograph, *Tumors of the Nervus Acousticus and the Syndrome of the Cerebellopontine Angle*³ published in 1917 by Cushing, reported on 30 cases approached through a suboccipital craniotomy. Each of these cases was far advanced by today's standards, all of these patients having severely elevated intracranial pressure, and half of them being afflicted with varying stages of blindness as a result of prolonged elevated intracranial pressure. By 1917 Cushing was able to lower the mortality of acoustic tumor surgery from an appalling 80 percent to a much more acceptable 30 percent. This was accomplished by wide decompression of the posterior fossa and extensive subtotal enucleation of the interior of the tumor. In most instances he felt that a total removal of this tumor was not possible.

Since 1917, tremendous strides in the diagnosis and management of these lesions have occurred. Otolaryngologists, neurosurgeons and neurologists have contributed generously to these advances. It remains, however, for an alert medical community to suspect this tumor in its early stages if the advances

*Research Director, Los Angeles Foundation of Otology.

**Neurosurgical Consultant, Los Angeles Foundation of Otology.

From the Otologic Medical Group and sponsored by the Los Angeles Foundation of Otology.

that have occurred will, indeed, be made available to these patients.

Diagnosis

The adaptation of microsurgical technique for the removal of acoustic tumors has made the diagnosis of these lesions while they are still small more than an academic exercise.⁴ Accordingly it will be the purpose of this section to emphasize those diagnostic features which may be detected early in the history of this tumor. Our discussion will summarize the abnormalities found in the following areas of diagnosis: clinical, audiologic, vestibular, radiologic, and neurologic.

Clinical

Acoustic tumors may occur in any age group. They are most commonly seen, however, in the 4th and 5th decades of life. There is no sex dominance.

The earliest symptoms are caused by disturbances of the 8th cranial nerve in both its vestibular and auditory branches. Tinnitus may be high-pitched and persistent. Hearing loss is insidious in onset and then progressive. While the tumor is small these patients have difficulty in understanding the meaning of words, rather than in the actual perception of sound. As the tumor enlarges, however, perception of sound also deteriorates.

Unsteadiness is commonly seen. This will be more pronounced on rapid positional change and under conditions of anxiety or fatigue. The unsteadiness is generally of brief duration. Over a period of time most patients compensate for it. Many patients who are seen in the late stages of their disease will have forgotten about it.

True vertigo, similar to that seen in Meniere's disease, has been found in 25 percent of our cases.

Pain and dysesthesias in the external auditory canal or behind the ear over the mastoid may be present.⁵ These sensory disturbances are felt to be due to pressure on the sensory portion of the seventh cranial nerve (*nervus intermedius*).

As the tumor enlarges and grows out into the posterior fossa, symptoms of an intra-

cranial neoplasm become apparent. The patient may complain of headache, difficulty with gait, visual impairment, ocular palsies, facial weakness, numbness and difficulty swallowing.

Audiologic

Acoustic tumors usually develop on the vestibular portion of the auditory nerve in the internal auditory canal. As the tumor enlarges, it causes pressure on the adjacent cochlear division. This results in abnormal audiologic function.

Tuning fork tests, tests of pure tone reception, speech discrimination, auditory fatigue, and loudness function, help to localize the retrocochlear site of the tumor.⁶

TUNING FORK TESTS

Patients with acoustic neuromas will show lateralization of the tone to the normal ear. Air conduction will be heard greater than bone conduction on the affected side. When the difference in hearing is marked between the two sides, masking of the normal ear must be carried out for tuning fork tests to have validity. A Barany noisemaker suffices very well for this purpose.

PURE TONE AUDIOGRAM

The patient with an acoustic tumor will show a sensori-neural type hearing impairment with the most pronounced loss being in the higher frequencies. A high-frequency loss has been found in 70 percent of our cases.

SPEECH DISCRIMINATION

The ability to understand the meaning of words is one of the earliest audiologic parameters to be affected by acoustic tumors. Speech discrimination measured by standard phonetically balanced word tests will show marked impairment. This is in contrast to patients with a conductive impairment and normal hearing patients who will show high discrimination. Patients with cochlear lesions, such as Meniere's disease, will occasionally show a moderate impairment in speech discrimination.

AUDITORY FATIGUE TESTS

Patients with normal hearing, or those with a conductive impairment, are able to hear continuous tones presented just above threshold for a prolonged period of time without developing significant auditory fa-

Fig. 1 — Iophendylate study of the posterior fossa showing defect in the contrast column adjacent to the right internal auditory meatus.

Fig. 2 — Middle fossa (subtemporal) approach to the roof of the internal auditory canal. Self-retaining retractor is in place elevating the dura overlying the temporal lobe. The internal auditory canal is exposed on the floor of the middle fossa.

tigue.

In sensori-neural impairment a varying amount of adaptation, or auditory fatigue, will occur, depending upon the location of the lesion. Auditory fatigue is minimal and usually limited to the higher frequencies in cochlear disorders. In cases of acoustic neuroma, there may be severe or total adaptation, as measured by the modified tone decay test or Bekesy Audiometry. In this latter test, the Type III and Type IV curves are characteristically seen.⁷

LOUDNESS FUNCTION TESTS

Patients with retro-cochlear lesions have normal responses to loudness function tests such as the alternate binaural loudness balance test and the short increment sensitivity index test. In contrast to this, abnormal responses are found in patients with cochlear lesions.

Vestibular

Testing the labyrinth with ice water will show hypoactivity in approximately 90 percent of patients.⁸ Of this group, 50 percent will have a functionless labyrinth.

Spontaneous nystagmus may be variable. In the early stages of this disease, it is often not found. An electronystagmograph can be used to detect spontaneous nystagmus which may not be apparent on clinical examination.

Radiologic

Carefully taken plain x-rays, including Stenver's projection, will show a difference in the diameter between the auditory meati. A difference of 1 millimeter is suspicious if this is accompanied by erosion or a difference in the shape of the two internal auditory canals.⁹

Positive contrast studies of the posterior fossa using iophendylate have increased the accuracy of radiologic diagnosis of these tumors to 95 percent. The tumor defect appears as an indentation in the iophendylate medium at the porus acousticus¹⁰ (Figure 1).

Neurologic

There are several tests which can be read-

ily carried out by the otolaryngologist and general practitioner in his office that will be very helpful in making the diagnosis of acoustic neuroma. Testing of the corneal responses can be done with a small wisp of cotton. The corneal response is one of the first neurologic reflexes to be blunted by an acoustic tumor.¹¹ In addition to this, testing the sensation along the posterior aspect of the external auditory canal will very often show impairment in these patients. This test can be performed with a blunt right angle hook.⁵

Spinal fluid protein is generally not elevated while the tumor is confined to the internal auditory canal, or only slightly protruding into the posterior fossa.¹² Elevation does occur, however, to a marked degree as the tumor enlarges and indents the adjacent brain stem.

Treatment¹³

The treatment for acoustic tumors is surgical with few exceptions due to severe infirmities or far-advanced age.

The goal of surgery should be total removal of the tumor within the framework of the following criteria:

1. Avoidance of further cranial nerve damage.
2. Adequate decompression of the posterior fossa.
3. Avoidance of injury to the brain stem or cerebellum.
4. Satisfactory access for removal of the tumor and management of any postoperative complications.

The operations that are in use today are of four types: (1) middle fossa approach, (2) translabyrinthine approach, (3) suboccipital approach, (4) combined suboccipital-petrosal approach (trans-sigmoid approach).

Middle Fossa Approach

The middle fossa approach (Figure 2) is a surgical technique designed to remove tumors confined to the internal auditory canal. This limited approach is indicated for small tumors only when hearing preservation or improvement is possible. It is accomplished

through a sub-temporal craniectomy with elevation of the temporal lobe of the brain. The internal auditory canal is exposed from above and removal of small tumor in the canal is carried out.

Translabyrinthine Approach

The translabyrinthine approach (Figure 3) is a direct surgical route through the mastoid and labyrinth to the cerebellopontine angle. It is used for removal of tumors of moderate size not associated with elevated intracranial pressure and not extending below the level of the jugular bulb. The facial nerve is identified early in the dissection prior to extensive tumor removal, allowing its preservation in most instances.

Fig. 3 — Translabyrinthine approach to the cerebellopontine angle. Tumor is visible beneath the cut dura lying above the jugular bulb. The facial nerve has been exposed in the internal auditory canal.

Fig. 4 — Combined approach to the cerebellopontine angle. In this case the sigmoid sinus has been divided.

Suboccipital Approach

The suboccipital approach to the cerebellopontine angle is carried out by removal of a portion of the lateral suboccipital bony plate. The intervening lateral cerebellar hemisphere is either reflected or partially resected in order to allow access to the tumor. This operation has been widely accepted in the past as the standard approach for all tumors in the cerebellopontine angle. It continues to be an excellent approach for large tumors.

*Combined Suboccipital-Petrosal Approach
(Trans-sigmoid Approach)*

The combined suboccipital-petrosal approach (Figure 4) to the cerebellopontine angle is carried out by extending the suboccipital bony opening forward over the sigmoid sinus to the internal auditory canal. The sigmoid sinus may be either ligated and divided or mobilized depending on the situa-

tion of the tumor. This operation allows wide decompression of the cerebellopontine angle, direct access to the tumor, and early exposure of the facial nerve. The dura overlying the cerebellum is kept intact in order to prevent operative injury to this structure.

Summary

It is only through a thorough understanding of the early changes that occur in patients with acoustic tumors and persistence in the evaluation of these challenging patients that we will be able to make this diagnosis while the tumor is still small. At this stage of its growth, it is most susceptible to eradication with a minimum of residual neurologic deficit.

The early changes caused by an acoustic tumor have been reviewed in relation to clinical, audiology, vestibular, radiologic, and neurologic aspects. Most of these diagnostic procedures can be carried out by the practicing physician in his own community.

Medieval Remedy for Dysentery

Against dysentery, a bramble of which both ends are in the earth, take the nether root, delve it up, cut nine chips with the left hand and sing three times the Miserere Mei Deus and nine times the Pater Noster; then take mugwort and everlasting, boil these worts and the chips in milk until they get red, then let the man sip at night fasting a pound dish full, let him rest himself soft and wrap himself warm; if more need be let him do so again; if thou still need do it a third time thou wilt not need oftener.*

Medicine is a science, acquiring a practice an art. — Anonymous

I'm supposed to get up and do things?

With my heart?

It's entirely natural—and may even be desirable—for the cardiovascular patient to be somewhat anxious about himself.

But when anxiety leads to unreasonable self-imposed limitations and restrictions . . . when it aggravates cardiovascular symptoms . . . when it interferes with restful sleep, measures to help alleviate the anxiety are probably in order.

One measure, of course, is reassurance. Another, adjunctive measure, is EQUANIL (meprobamate).

Over a decade of experience has shown that EQUANIL (meprobamate) is generally well tolerated as well as effective. Side effects are usually limited to transient drowsiness; serious, therapy-interrupting side effects are rare.

Cautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use may result in dependence or habituation in susceptible persons—as ex-addicts, alcoholics, severe psychoneurotics. After prolonged high dosage, drug should be withdrawn gradually to avoid possibly severe withdrawal reactions including epileptiform seizures. Side effects include drowsiness and, rarely, allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute non-thrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. Meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Warn patients of possible reduced alcohol tolerance. Should drowsiness, ataxia, or visual disturbances occur, dose

should be reduced. If symptoms persist, patients should not operate vehicles or dangerous machinery. A few cases of leukopenia, usually transient, have been reported following prolonged dosage. Other blood dyscrasias—aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia—have occurred rarely, almost always in the presence of known toxic agents. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. Prescribe very cautiously for patients with suicidal tendencies. Suicidal attempts should be treated with immediate gastric lavage and appropriate supportive therapy.

Contraindications: History of sensitivity to meprobamate.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

Transsphenoid Hypophysectomy

WILLIAM W. MONTGOMERY, M.D.*
Boston, Massachusetts

THE TRANSPHENOID approach to the pituitary allows for a lower morbidity and mortality rate as compared with the anterior craniotomy route. There is less chance for injury to the optic chiasm. Postoperative complications such as seizures, extradural hematoma, brain damage, and cerebral edema are rare. The convalescent period following the transsphenoidal route for hypophysectomy is usually quite short.

There are a number of routes and modifications for the transsphenoidal hypophysectomy.

Operative Routes

Trans-Septal-Sphenoidal Hypophysectomy

This operation was pioneered by Oscar Hirsch in 1910. Cushing (1912) later used a sublabial modification of this route. Heck (1960) was the first in this country to use the transseptal approach for the treatment of advanced carcinoma of the breast. The main objection to this route is that it is a long narrow approach. Two instruments cannot be used simultaneously, and the dissecting microscope cannot be employed. It is, however, still used by many surgeons because of its being a direct midline dissection.

Transantroethmoidosphenoidal Hypophysectomy

Hamberger (1961) used this approach in a large series of patients with remarkable success. For most surgeons this is a long oblique route to the hypophyseal fossa. It also has the disadvantage of increasing the hazard of postoperative infection, for the oral route in some cases is potentially a septic area.

Transnasal Osteoplastic Hypophysectomy

Macbeth (1962) devised a unique direct midline approach using an osteoplastic skin flap based at the root of the nose. The only

*Surgeon in Otolaryngology, Massachusetts Eye and Ear Infirmary and Massachusetts General Hospital and Assistant Professor, Harvard Medical School.

disadvantage here is that it leaves undesirable scarring of the nasal bridge. Those who perform this operation, however, indicate that this is not a factor when treating advanced carcinoma of the breast.

Transethmoidosphenoidal Hypophysectomy

This technique for hypophysectomy has been used since the turn of the century. Chiari in 1912 described this method for the removal of a pituitary adenoma. A few of the otolaryngologists who deserve credit for improving the techniques for this approach are Nager (1940), Bateman (1962), and James (1964). They have used this operation because it is the shortest route to the hypophysis with a wide field. It permits easy manipulation of instruments, and more than one instrument can be used simultaneously. One instrument may be inserted by way of the nasal cavity and another by way of the operative field. The advent of the surgical microscope has also increased the popularity of the transethmoidosphenoidal hypophysectomy.

The *transethmoidosphenoidal* approach for hypophysectomy has been used for solid and cystic pituitary tumors, palliative therapy for advanced breast carcinoma, diabetic retinopathy, and advanced prostatic carcinoma. Cystic tumors can easily be marsupialized. Solid tumors can be resected and/or decompressed. Most authors, Riskaer (1961) and Bateman (1962), for example, report 60% to 80% transient remissions when treating generalized metastases from carcinoma of the breast with hypophysectomy. Patients with breast carcinomatosis so weak that they could hardly turn in bed have had dramatic results following hypophysectomy. Similarly good results were obtained after hypophysectomy for diabetic retinopathy.

Preoperative Management

A team consisting of a neurologist, an endocrinologist, and a surgeon is essential for the proper management of the patient during the preoperative and postoperative periods. A rhinologist who attempts a hypophysectomy without the assistance of these two specialties is only inviting disaster. If

neurological and endocrinological work-ups have not been carried out prior to the patient's admission to the hospital, he should be admitted several days prior to surgery so that these may be accomplished. The neurologist will conduct a careful neurological survey which, in the case of pituitary tumors, should include radioactive scanning, pneumoencephalogram, and arteriograms. The endocrinologist will obtain the preoperative endocrine balance and prescribe the necessary hormones during the preoperative, operative, and postoperative periods.

Procedure

A complete external ethmoidectomy is performed. It is most important that the patient's head be secured in a supine position with the aid of sandbags. A septal mucosal flap is constructed before entering the anterior wall of the sphenoid. This flap is reflected into the nasopharynx in readiness to cover the defect in the posterior wall of the sphenoid sinus upon completion of the hypophysectomy.

Entering the Sinus

The right sphenoid sinus is entered and the entire anterior wall removed. The bony nasal septum is left intact as an accurate guide to the midline. On the other hand, a small portion of the posterior nasal septum may be removed for a wider exposure, without destroying its usefulness as a midline guide.

Dissecting Microscope

The dissecting microscope is employed for the remainder of the operation. The bulge of the sella turcica can be seen on the posterior wall of the sphenoid sinus. The midline is again checked by using the posterior aspect of the nasal septum as a guide. If the anatomical relationships are doubtful, x-rays may be taken with a portable machine using metallic probes as pointers or lead-shot attached to suture material.

Entering the Dura

A small opening is made in the posterior wall of the sphenoid (anterior wall of the

sella turcica) with a curette or a rotating burr. This is enlarged by using various rongeurs. Either a vertical or a cruciate incision is made in the dura; the pituitary or tumor thereof is then removed by using suction and various dissectors.

Closure of the Defect

Following the completion of the pituitary surgery, the fossa is packed with gelfoam saturated with thrombin solution if there is any bleeding or spinal fluid leakage. Muscle

or adipose tissues may also be used for this same purpose. The septal mucosal flap is elevated from the nasopharynx and reflected into the cyst cavity rather than used to cover the defect in the posterior wall of the sphenoid sinus. This is done to ensure marsupialization of the cyst. A single layer of absorbable gelatin sponge is placed on the flap prior to its being packed in place with iodoform gauze which has been impregnated with chlortetracycline ointment. The packing is removed on the fifth postoperative day.

Celsus* Eponyms

Celsus is notable for the classic description of inflammation, familiar to every medical student: redness, swelling, heat and pain (rubor et tumor, cum calore et dolore). His reference to "pus discharging from the ear, leading to insanity and death," is an early recognition of meningitis. His "distemper seated in the large intestine principally affecting that part where I mentioned the caecum to be, accompanied by violent inflammation and vehement pains, particularly in the right side," is an unsurpassed description of a disease which was supposed to be discovered in modern times — appendicitis. He was the first to mention that a vessel may be ruptured within the cranium, without fracture or depression; the first to use such terms as heart disease (cardiacus) and insanity (insania), and the first to describe circular amputation by a single sweep of the knife. He considered amputation "the last sad remedy," permissible only in gangrene; circular amputation is still known as Celsus' operation.

Other eponyms are in dermatology, for Celsus described forty skin diseases: severe acute papular eczema is called Celsus' papules, anesthetic leprosy is Celsus' vitiligo, the soft chancre is known as Celsus' chancre, suppurating ringworm of the scalp is known as Celsus' kerion, and the ever-famous condition of patchy baldness (alopecia areata) is not less distressing because it bears the classic name of Celsus' area. He was a pioneer in the history of medicine, and in such diverse fields as dentistry, laryngology, ophthalmology, lithotomy and plastic surgery — reparative work was needed by those Jews who wished to hold office among the Romans and could not do so if they lacked a prepuce.**

Pharyngo- Tubo- Tympanic Disease

Management of

PHILIP E. MELTZER, M.D.*
Boston, Massachusetts

THERE IS A general impression that patients suffering from tubotympanic disease are on the increase, particularly patients with so-called "secretory ear" of various types. There are many good reasons why this may be so. The principle reason is that there is much better general understanding of the condition so that the correct diagnosis is made more frequently. This condition existed in the past but the symptoms were generally ignored, particularly in the "secretory ears" in young children.

Acute Suppurative Otitis Media

In the era before the sulfonamides and antibiotics, a child with an upper respiratory infection who developed pain in the ear usually developed an acute suppurative otitis media. The drum membrane would either rupture spontaneously or would have to be opened. With nothing to assist the child other than ear drops and a nasal spray, it was not surprising that "secretory otitis" was much less common than acute suppurative otitis media. The mechanics of effusions in the middle ear have been well known by the otologist for over seventy-five years. This was not true, however, of the general medical fraternity, including pediatricians and general practitioners. In fact, there were not too many practitioners in the 1915-1940 era who were able to see a drum membrane well enough to determine what was behind it. This remark is no reflection upon their ability as physicians, as the diagnosis of tubotympanic disease was not generally taught. Before the sulfonamides and antibiotics the focus was on acute suppurative otitis media. But in the last two decades there has been a complete change as far as the pediatrician and practitioner are concerned; they are now well able to diagnose other middle ear conditions by otoscopy.

*Posthumous. Clinical Professor Emeritus Otolaryngology, Harvard Medical School, 1961.

Nasopharynx and Eustachian Tube

A person with a normal functioning eustachian tube should be able to equalize the air pressure in the middle ear as against that of the outer atmosphere. Every time the palate is in motion, as in the act of swallowing, talking, yawning, the tube opens and closes, thus permitting air to enter and leave the middle ear. When, for one reason or another, the mucosa of the nasopharynx and eustachian tube becomes edematous, the swelling shuts off the airflow to the middle ear. The cause of the tubal obstruction may be hypertrophied adenoid, infection, or allergic edema with or without infection. If the tube is completely or partially occluded, symptoms such as a sense of fullness, tinnitus and slight deafness will result. If infection is the cause of the tubal obstruction and the infection extends to the middle ear, a more aggravated condition results. Pain occurs and the fluid in the middle ear changes in character to exudate.

Tubal Obstruction

The three most common causes of tubal obstruction are:

1. Infection of the mucous membrane in the nasopharynx.
2. Allergy.
3. Mechanical obstruction due to hypertrophied adenoid (particularly in children).

INFECTION

There are other causes, however, such as nasopharyngeal tumor, but the above three are most numerous. In children, the most frequent cause is the adenoid. Because of size this may be a purely mechanical obstruction. In these patients, relief is best accomplished by the thorough removal of the adenoid, particularly from the region of the fossa of Rosenmueller, the space just behind the torus of the tube, and from the torus of the tube itself. Despite thorough removal of the nasopharyngeal lymphoid tissue, recurrences are not uncommon. Susceptibility to middle ear conditions is an individual consideration, as not every child responds to nasopharyngeal infections in the same way.

Some children never have middle ear problems of any kind, yet have a huge adenoid, an allergy, and frequent postnasal infections. Other children have a small or no adenoid, yet their reaction to even the mildest infection is immediate tubal obstruction and blocked ears. This is also true in some adults. In many patients there is a strong family predilection related to inherent anatomic and physiologic factors.

ALLERGY

Allergic reaction of the mucosa in the middle ear and eustachian tube can occur as a part of an upper respiratory allergic state. In allergic children with nasopharyngeal infection the tissues respond poorly to treatment. On the other hand, treatment generally is quite effective in children with normal mucosa. The tissues in allergic children are already slightly edematous and when infection is superimposed upon their allergic membrane the edema is excessive, with notable infiltration by lymphocytes, plasma cells, and eosinophiles. One may control the infection; but resolution is slow and it takes a long time for the edema to be reduced to the point at which the flow of air to and from the middle ear proceeds normally. In some children the tube does not open regardless of treatment. These are the problem cases which require special management.

Manifestations

When acute serous otitis media becomes chronic it results in aggravated symptoms of deafness, tinnitus, sense of fullness and occasionally vertigo: symptoms which may persist for weeks and even months without pain.

The otoscopic picture is not difficult to discern. The drumhead is retracted. There may be a light pale yellowish tinge to the fluid as seen through the drumhead. The malleus in long-standing cases appears to be rotated, and the posterior handle of the malleus seems to stand out as a whitish chalk-like line. One may occasionally see the hairline of a fluid level, and if air enters the ear then small bubbles are visible through the drumhead, particularly during the act of swal-

lowing or yawning.

It must be remembered that a great many children with acute serous otitis media never come to the attention of the doctor at all. In these patients the acute inflammation of the nasopharynx and eustachian tube subsides, edema is reduced, air enters the ear, and drainage of the fluid takes place spontaneously through the tube. If the patient "burps" or blows his nose, air forcefully enters the middle ear. A "snap" in the ear is experienced and hearing suddenly returns. As has been said, it is with the patient with chronic or recurrent secretory otitis that the problem of management arises. As the negative pressure becomes more and more intense, a transudate accumulates in the middle ear from cells and capillaries of the middle ear mucosa.

"Glue Ear"

One form of chronic middle ear fluid that is commonly seen and has given rise to considerable discussion as to management is the mucoid or "glue ear." In this type of middle ear accumulation it is my firm belief that there has been inflammation of the middle ear mucosa, however mild. In these patients, however, the inflammation is frequently not sufficiently severe to require medical care. The middle ear becomes filled with a sticky tenacious mucous that gives a sense of fullness and increasing deafness. When this occurs the child is belatedly brought to the physician. The drum is dull, usually with some fullness around the periphery. The outline of the malleus may or may not be seen, and there is a definite lack of mobility of the drum when tested by positive and negative pressure. These are the difficult cases. A simple incision and aspiration may, in certain cases, if followed by politzerization of the eustachian tube, result in rapid improvement. Generally, however, the tube is still partially or completely obstructed and the secretions are too tenacious to drain through the eustachian tube. In those cases that fail to clear up after incision and withdrawal of the mucous by suction, a different management is required. These patients will require constant ventilation by means of a

teflon or polyethylene tube inserted through the drum into the middle ear and left in place until such time as the eustachian tube functions normally.

Severe Inflammatory Otitis Media

Another cause of "mucoid ear" is the oversight of the attending doctor in relation to management of a more severe inflammatory otitis media. Pain, fullness and deafness are present and the pain is severe enough to have the doctor called in attendance. He will usually give an antibiotic which may relieve the pain, but the fullness and deafness persists. The inflammation subsides with the antibiotic; but normal landmarks of the drum membrane are obscured and the middle ear fills with secretion. I am not describing the early stage of a severe acute otitis media where the drum is bulging and is intensely red, with continuous severe pain, fever, etc. This is a picture of acute otitis media that needs prompt incision and drainage. I am talking now of the acute middle ear that has subsided with antibiotics. These are the cases most commonly neglected. After such an acute otitis media every child or adult should have a follow-up examination for hearing loss.

Discussion

Acute Serous Otitis Media

Now let us discuss management in more detail — first, that of the acute serous otitis media or the noninflammatory type due to tubal obstruction at its orifice. This type of secretory otitis usually is greatly relieved by adenoidectomy.

In allergic children, even when the adenoid is not enlarged, infection increases the existing edema, which in turn obstructs the tube. This type of case can be treated conservatively in a child. The fluid in the middle ear does not require immediate aspiration. Shrinking solution can be supplied to the mucosa of the nose (Afrin, Neosynephrine, or any of the other preparations that are in common use). Antihistamines in combination with the shrinking agents can be quite effective. If the tube opens, the fluid will

drain and hearing will improve. If the serous otitis recurs and adenoid is present, a careful removal by direct visualization of the postnasal space and removal of all lymphoid tissue from the fossa of Rosenmueller and from the torus of the tube will generally cure the recurrent condition. This is done by elevating the soft palate so that the entire postnasal space is visualized. The main mass of adenoid is removed and then the remaining lymphoid tissue from the areas just mentioned with special punches. This includes the bands of lymphoid tissue that lie along the posterior pillar of the tonsil.

Tenacious secretions in the nose can be removed at home by using a large rubber bulb with an acorn shaped nasal tip placed in one nostril and closing off the other. When the infection subsides, gentle politizerization of the middle ear or auto-inflation can be performed. In other words, one should be patient with the acute serous effusions in children due to mechanical causes or mild infection of the postnasal space.

In recurring acute serous otitis or chronic serous otitis with or without exudate, something more drastic must be done if, after incision and aspiration, the transudate or exudate recurs. A ventilation tube should be inserted in the middle ear through the drum membrane and left there until such time as the acute or subacute inflammation in the nasopharynx subsides and normal aeration of the middle ear takes place.

Acute Suppurative Media

In the acute suppurative infections of the middle ear, the infecting organism should be determined by culture and the most effective antibiotic prescribed. This should be continued until there is complete resolution of the middle ear infection as indicated by return of landmarks and normal hearing.

It does not matter how skillfully one removes the adenoid, this tissue tends to regenerate in certain patients. This is particularly true in allergic children. Slight as this regeneration or hyperplasia may be, it is sometimes sufficient, when infected, to be the basis for recurrent obstruction of the

eustachian tube. In children with recurrent otitic problems, where I have personally performed the adenoidectomy, I am not at all reluctant to advise re-examination of the postnasal space under an anesthetic. I am no longer embarrassed by the necessity of removing a regrowth of lymphoid tissue. Secondary adenoidectomy is not an operation to be performed in a casual manner. The recurrent tissue must be trimmed flush with the basement membrane. Furthermore, allergic children must not be treated with indifferent allergic management, or serous otitic recurrence will be the rule.

Adhesive Otitis Media

Before concluding I must speak of a middle ear problem that is most serious: the so-called adhesive otitis media wherein adhesions bind the ossicles to each other or to the medial wall of the middle ear, a condition resulting from repeated infections of the middle ear. In my experience, I have yet to witness an adhesive otitis media following a true serous otitis media. Where there is no inflammatory ulceration there is no break in the epithelium, and where there is no break in the epithelium of the mucosa on the medial wall or the inner surface of the drum membrane, there will be no adhesions. Frequently, middle ear examination at the time of stapedectomy reveals bands of mucous membrane stretching across the chamber. These bands for the most part are normal. They are usually the result of the incomplete resolution of the myxomatous tissue present at birth before pneumatization of the middle ear chamber. These bands do not interfere with the mobility of the ossicular chain and they give rise to no symptoms whatsoever. The bands resulting from ulcerative inflammatory involvement of the middle ear mucosa, on the other hand, represent meaningful pathology. They may cause the malleus to be retracted against and adherent to the promontory. The head of the malleus and incus may similarly become fused. Placing a drainage tube in the middle ear will not alone be effective. The chamber must be forcibly aerated and the adhesive process disrupted.

Irradiation

A word about irradiation of the nasopharynx after adenoidectomy for recurrent growth is in order. For years I have used irradiation after removal of recurrent growth and felt that it was quite effective on lymphoid tissue. I am now somewhat reluctant to treat these young patients with small doses of x-ray because of the dangers that have been attributed to irradiation, even in relatively "safe" doses. I have never felt that the use of radium applicators in this area was wise.

Allergic Management

I close by re-emphasizing the need of good allergic management and thorough removal of lymphoid tissue in children as the prime treatment of tubotympanic dysfunction. When necessary the introduction of an indwelling microtube through the drumhead will provide continuous aeration of the middle ear chamber. In children to a degree, but particularly in adults, persistent serous otitis media should alert the clinician to the possibility of nasopharyngeal malignancy.

Medical Pomposity

With erudite profundity,
And subtle cogitabundity,
The medical expert testifies in court;
Explains with ponderosity,
And keen profound verbosity
The intricate nature of the plaintiff's tort.

Discoursing on pathology,
Anatomy, biology,
Opines the patient's orbit suffered thus:
Contusions of integuments
With ecchymose embellishments,
And bloody extravasation forming pus.

A state of tumerosity
Producing lachrymosity,
Abrasion of the cuticle severe,
All diagnosed externally,
Although he feared, internally
Sclerotic inflammation might appear.

The jury sits confused, amazed,
By all this pleonasm dazed,
Unable to conceive a single word,
All awed, they think with bated breaths
The plaintiff died a thousand deaths —
What agony and pain he had endured!

But then the counsel for defense,
Devoid of garrulous eloquence,
Asked, "Isn't it true that all you testified
Means merely from a punch or two
The plaintiff's eye was black and blue?"
"Yes, that's correct," the doctor meekly sighed.

Tympanoplasty for Chronic Otitis Media

FREDERICK R. GUILFORD, M.D.*
Houston, Texas

IN SPITE of antibiotics, chronic ear suppuration following acute otitis media or trauma, or in association with cholesteatoma, remains a common clinical finding in the practice of otolaryngology. A high incidence of this condition will be found in general medical practice, provided a careful examination is done with a magnifying otoscope.

Physical Findings

Intermittent or persistent purulent discharge may be present especially following bathing, swimming, or upper respiratory infection and hearing loss in the involved ear. On otoscopic examination relatively large areas of the tympanic membrane may be absent without causing significant hearing impairment, but the loss of ossicular continuity, which may be a late sequela, usually results in hearing loss.

Indications for Surgery

While it would appear that antibiotics could control all types of infection, it is now apparent that these drugs alone are inefficient in controlling chronic suppuration of the middle ear and mastoid. Effective treatment of the condition often requires tympanoplasty or surgical removal of the suppurative processes and repair of the ossicular chain and tympanic membrane. The aims of tympanoplasty are control of the suppurative process and reconstruction of the damaged conduction mechanism; the ossicular chain and tympanic membrane.

Control of Suppuration

Conservative measures such as frequent aspiration of the middle ear followed by irrigation with appropriate antibiotic solution will often control the suppurative process prior to surgical reconstruction; however, direct surgical measures, such as mastoidectomy, removal of granulations from the middle ear, or curettage of the hypotympanic cells may

*Clinical Professor of Otolaryngology, Baylor University College of Medicine.

be necessary as the initial step in the reconstructive process. The use of the binocular operating microscope aids materially in this surgery. Conservation of tissue commensurate with accepted surgical principles is the rule in order to restore as near normal functional anatomy as possible. The external auditory canal is either left intact or reconstructed in order to avoid a postoperative

mastoid cavity. The reconstructed tympanic membrane, then, is a barrier to suppuration as in the normal condition since its presence protects the middle ear from contamination.

Repair or Reconstruction of the Ossicular Chain

Repeated infections of the middle ear, as may occur with perforation of the tympanic membrane, may result in disruption of the ossicular chain. The disruption is usually due to necrosis of the long process of the incus and results in dissolution of the incudostapedial articulation. The disruption may also affect the manubrium of the malleus and occasionally the arch of the stapes (Figure 1). When a cholesteatoma is present, erosion of the ossicles and adjacent osseous tissue in the temporal bone may occur. A persistently perforated ear drum may be complicated by invasion of squamous epithelium into the middle ear and mastoid and development of this destructive process. Generally, this complication is more frequently found in perforations located in the peripheral areas of the tympanic membrane. A cholesteatoma may cause other serious complications, such as intracranial lesions, but these are rare.

The control and removal of cholesteatoma and other irreversibly diseased processes of chronic suppuration is the prime objective of temporal bone surgery. In the last decade techniques of reconstruction of the tympanic membrane, ossicular chain and posterior wall of the ear canal (in order to avoid a mastoid cavity) have been developed. Radical removal of irreversibly diseased tissue but retention of functional structures is the rule. In addition, recent results suggest that homograft ossicles (especially the incus may be used to replace diseased ossicles or those which have been destroyed.

Satisfactory results are not obtained following the use of plastic materials to reconstitute the ossicular chain, and it may be necessary to reposition the incus or malleus in order to form an intact conduction mechanism between the tympanic membrane and mobile stapes to afford good hearing results (Figure 2). When a member of the chain is

Fig. 1-a reveals the meatal flap and posterior one-half of the tympanic membrane elevated (1), large central perforation (2), and intact incudostapedial joint (3).

Fig. 1-b, the elevated meatal flap and posterior one-half of the tympanic membrane (1), perforation (2), and disrupted incudostapedial joint (3) are shown.

irreversibly destroyed, it can be replaced by cortical bone fashioned from an adjacent area of the skull or more recently by the homograft ossicle which is preserved by freezing. Wire can also be used successfully to bridge small gaps in the ossicular chain, especially between the malleus and the stapes.

Repair of the Tympanic Membrane

Partial or total defects of the tympanic membrane may be reconstructed providing the suppuration and related processes have been successfully controlled. The operation is usually performed as a one stage procedure,

Fig. 2 — An example of reconstruction of the ossicular chain by repositioning of the incus shown in lateral and cross-sectional views (previously published in the *Laryngoscope* 75:236, February 1965).

Fig. 3-a illustrates the large kidney shaped perforation in the tympanic membrane and a portion of the adjacent wall of the external auditory canal.

but occasionally the reconstructive portion of the operation is performed later.

Early efforts to use the skin from the post-auricular area or extremities for repair of the tympanic defect were not completely successful because of a tendency for complications, such as the occurrence of epidermoid cyst and dermatitis of the graft in relation with the skin appendages. The skin of the ear canal has proven to be more adaptable when combined with a thin layer of fibrous tem-

Fig. 3-b shows the incisions for removal of the skin from the medial portion of the external auditory canal and tympanic remnant.

Fig. 3-c, the skin has been removed medial to the incisions in continuity with the skin on the tympanic remnant.

Fig. 3-d, an appropriate sized piece of temporal fascia has been replaced on the tympanic remnant covering the perforation.

Fig. 3-e illustrates the placing of the skin from the external auditory canal over the fascia and adjacent canal.

poral fascia tissue. With this combination of tissues, it is possible to afford reconstruction of the three layers normally present in the tympanic membrane (Figure 3).

The skin of the lateral surface of the tympanic remnant and medial part of the external canal is elevated as a flap, or completely removed, and the middle ear carefully inspected for invading squamous epithelium or other pathologic processes. A thin layer of temporal fascia is obtained through existing or separate incisions. The fascia is tailored to fit the area precisely and is then placed over the perforation and the denuded surface of the tympanic remnant or overlapping onto the adjacent denuded external auditory canal. The skin of the external canal is then replaced in such a fashion that it overlaps the layer of the fascia. The squamous epithelium then migrates during the healing period across the lateral surface of the fascial graft, and the continuity of the tympanic membrane is again intact. The undersurface of the fascial graft is covered by the migrating mucous membrane from the middle ear, and the three layers of the tympanic membrane, namely the mucous membrane, the fibrous layer, and the external skin, are restored.

Conclusions

It is evident that tympanoplastic surgery affords the possibility of hearing restoration as well as control of infection in the presence of the persistent perforation of the tympanic membrane due to traumatic or chronic suppurative processes. The application of these reconstructive measures in temporal bone surgery is a significant advance in otolaryngology, in the tradition of the remarkable development of surgical rehabilitation in modern medical practice.

Bedridden Truth

It is the most useful prerogative of genius to rescue truths from the neglect caused by the very circumstance of their universal admission. Truths, of all others the most awful and interesting, are too often considered as so true that they lose the power of truth, and lie bedridden in the dormitory of the soul. — Samuel Coleridge

Partial Laryngectomy

JOSEPH H. OGURA, M.D.*
FLOYD BARNHILL, M.D.**
St. Louis, Missouri

PARTIAL LARYNGECTOMY refers to the broad term covering hemilaryngectomy for cancer of the true cord; subtotal supraglottic laryngectomy for cancer of the epiglottis, and partial laryngopharyngectomy for cancer of the pyriform fossa or base of tongue.

Malignant tumors arising in these areas behave differently from one another with reference to structures invaded, aggressiveness, and prognosis. All of these partial laryngectomy operations are covered under the term "conservation surgery."

This paper will deal with the surgical results to date by comparing cancers in four primary locations: one of the cord treated by irradiation and hemilaryngectomy and three managed by supraglottic laryngectomy or subtotal pharyngolaryngectomy. The cases have been followed for two to eleven years. The absolute survival rate includes only those patients living and free of tumor. The survival rate includes both those patients free of disease and those who died of intercurrent disease. Any patient who expired within two months of surgery was included in the death of disease group.

Cancer of the Larynx

Cancer of the larynx is divided into four groups:

Cancer of the glottis refers to neoplasms restricted to the true membranous cord, vocal process on one or both sides. The floor of the ventricle is included in the glottic group and for a distance of one centimeter below the medial border of the cord, where the intrinsic muscles end.

Cancer of the subglottis refers to primary lesions immediately beneath the vocal cord in the anterior or lateral portions down to the lower border of the cricoid cartilage.

Cancer of the epiglottis, or supraglottis,

*Lindburg Professor and Head, Department of Otolaryngology, Washington University School of Medicine, St. Louis.

**Instructor of Otolaryngology, Washington University School of Medicine.

belongs with the larynx group and is restricted to the laryngeal surface of the epiglottis and the false cords or ventricular band.

Transglottis cancer refers to lesions crossing the ventricle.

Carcinomata of the Laryngopharynx

Carcinomata of the laryngopharynx are divided into two groups on the basis of anatomical location, biologic behavior, incidence of cervical metastases and eventual prognosis. Because of the characteristics indigentous to each of the following groups, surgical therapy must be altered accordingly.

Superior hypopharyngeal carcinoma includes lesions of the lingual surface of the epiglottis, the valleculae and the base of the tongue.

Inferior hypopharyngeal carcinoma includes lesions of the pyriform fossa, aryepiglottic folds and posterior pharyngeal wall.

Cervical Node Metastases

Cancer of the true cord metastasizes infrequently to the neck, whereas cancer of the epiglottis metastasizes more frequently. Carcinomata of the laryngopharynx are associated with a high rate of metastases to cervical lymph nodes.

Radiotherapy has been shown to yield poor results in controlling cervical metastases.^{4,7} Therefore it is mandatory that surgical treatment of carcinoma of laryngopharynx be based on a knowledge of the probable incidence of metastases and include a method of controlling them. It is now generally accepted that radical neck dissection in continuity with resection of the primary tumor is the procedure of choice when the presence of cervical metastases is probable.^{10,12,14}

Every patient with palpable cervical lymph nodes associated with a lesion in the laryngopharynx should have radical neck dissection performed at the time of resection of the primary tumor. A question arises as to what to do in the absence of cervical adenopathy. The incidence of occult metastases associated with supraglottic carcinoma is 10% and does not justify the performance of elective neck

dissection. However, an incidence of 40% occult metastases from carcinomata of the inferior and superior hypopharynx is high enough to justify elective radical neck dissection. It is well recognized that waiting for the appearance of metastases and performing staged surgery result in a higher incidence of local recurrences.¹⁰ Patients with occult metastases with elective neck dissections have an increased survival over patients who have had therapeutic neck dissection.^{9,12,14}

Bilateral cervical lymph node metastases have occurred infrequently in our patients with occult cervical metastases on the side of the lesion. They are, however, fairly common in patients with clinical metastases on the side of the lesion. In almost all cases contralateral metastases are clinically present when the patient is first seen. Of five patients who had staged neck dissections for cervical metastases from inferior hypopharyngeal carcinoma all have died of disease within twelve months, whereas four of six patients who had one-stage bilateral neck dissection with resection of a hypopharyngeal tumor are alive and well two or more years postoperatively. We therefore advocate one-stage bilateral neck dissection with resection of the primary lesion when bilateral cervical adenopathy exists.

Treatment of the Primary Lesion

Radiotherapy has yielded good results for cancer of the true cord when the tumors were small and restricted to the membranous portion. On the other hand, irradiation failures were noted when the lesion crossed the anterior commissure, extended into the subglottis more than 5 mm., and involved the vocal process. These more extensive cordal lesions should be treated by hemilaryngectomy.

Radiotherapy has yielded uniformly poor cure rates in the treatment of laryngopharyngeal lesions regardless of the site of the lesions. Radiation cure rates of 20 to 25% for supraglottic carcinoma and smaller figures for hypopharyngeal carcinoma have recently been reported.^{2,3,5}

The argument that laryngectomy can al-

ways be performed should radiotherapy fail is fallacious. In this instance one must deal with the complications of irradiation-induced tissue changes as well as with an altered resistant tumor cell population which often extends far beneath apparently normal mucosa. As a result, secondary surgery does not yield as good cure rates as primary surgery. There is, however, some evidence that planned preoperative radiotherapy followed immediately by surgical resection may have merit.^{8,15,16}

Surgical therapy for carcinoma of the laryngopharynx has, in the past, consisted almost entirely of widefield total laryngectomy or total laryngopharyngectomy. Since involvement of the glottis is a late development in this type of cancer, total removal of the larynx seems an unnecessarily radical procedure. It has been our experience that as many as 50% of lesions of the laryngopharynx may be removed with their lymphatic drainage tracts by *subtotal* laryngeal and pharyngeal resection and radical neck dissection.

Involvement of the pre-epiglottic space by laryngopharynx cancer is very common and is the most frequent cause of failure in too conservative surgical resection. It is imperative that the hyoid bone and pre-epiglottic space be removed in every case. This is accomplished by both total laryngectomy¹⁰ and subtotal laryngectomy.¹³

Subtotal laryngectomy avoids the stigma too of loss of phonation and permanent tracheostomy and in our hands has given as good or better cure rates than total laryngectomy.

The success of subtotal laryngectomy is dependent upon careful patient selection. The procedure is not suitable for very large

extensive lesions. The preoperative laryngograms and laryngoscopy are essential. Cartilage destruction and extensive glottic involvement with cord fixation are contraindications to this operation.

The technical factors important in the surgical resection and the rehabilitation of deglutition have previously been reported.^{12,13,17,19}

Results of Treatment of Cancer of the Glottis Treated by Irradiation and Hemilaryngectomy

A series of 50 cases of glottic carcinoma treated by irradiation alone has yielded an overall absolute five-year cure rate of 78% and a tumor survival rate of 92%.¹⁸

It must be understood that these cases were first screened for suitability. Small lesions of the membranous cord were predominant. Failures were principally large glottic tumors involving the vocal process, subglottis or anterior commissure.

We have performed seventeen hemilaryngectomies after irradiation failed, with an absolute two-year salvage rate of 65%. Two more patients were salvaged by total laryngectomy and four died of intercurrent disease. This means that only one of the 17 has died of his cancer (Table 1-A) since this data was compiled.

TABLE 1-A
Survival Rate of Hemilaryngectomy after Radiation Therapy Failure

	2 years	5 years
Living and well	11	2
Living with disease	1	0
Death without disease	4	3
Death with disease	1	0
Absolute survival	11/17 (65%)	2/5 (40%)
Tumor survival	15/17 (88%)	5/5 (100%)

TABLE 1-B
Survival Rate of Hemilaryngectomy

	2 years	5 years
Living and well	46	16
Living with disease	0	0

Death with disease	7	6
Absolute survival	46/60 (77%)	16/22 (73%)
Tumor survival	53/60 (88%)	16/22 (73%)

The results of 60 hemilaryngectomies, in previously untreated patients, yielded an absolute two-year survival rate of 77% and a tumor survival rate of 88% (Table 1-B). See Table 2 for an outline of the failures. The results of laryngofissures at this institution are not included.

Results of Treatment of Carcinoma of the Larynx or Laryngopharynx by Total Laryngectomy and Subtotal Laryngectomy

Supraglottic Carcinoma

A series of 39 consecutive supraglottic carcinomata treated by widefield total laryngectomy and radical neck dissection at our institution were recently reported.¹ The tumor survival rate at five years was 80%.

Since 1958 we have performed a subtotal supraglottic laryngectomy on supraglottic carcinoma whenever possible. The results of this type of surgery are shown in Table 3 and they are seen to be comparable to those obtained by total laryngectomy.

TABLE 2
Analysis of Failures (Hemilaryngectomy)

Cause of Failure	1	2	3	4	5	6	Total
Death with Disease	Follow-up in Years

Death without Disease							
Second primary	1	1					2
Myocardial infarction	2			1			3
Congestive heart failure	1						1
Dissecting aneurysm		1					1
							14

The most important point in the analysis of the failures in this group is that only five patients of 65 have had recurrence of their cancer. The tumor survival rate was 77%. Three patients had cervical node metastases with persistent disease in the lateral neck; one patient had late distant metastases, and none developed a recurrence at the site of the larynx. It has been our experience that patients dying of persistent carcinoma of the laryngopharynx will manifest evidence of persistence within twelve months of the primary surgical procedure in over 90% of the cases.

Supraglottic subtotal laryngectomy is a valid cancer-excising surgical procedure which carries small risk of local persistence of disease if carefully done on selected patients. At the same time normal phonatory mechanisms are retained without loss of normal deglutition (Table 4).

Carcinoma of Inferior Hypopharynx

In a series of 59 consecutive patients with carcinoma of the inferior hypopharynx treated by total laryngectomy and radical neck dissection, the absolute five-year survival rate was 30%. Of the 28 failures, 16 patients died of persistent disease. Eight developed recrudescence in the operated side of the neck, and six developed recrudescence in the pharynx, with two patients dying of distant metastases. Fifteen of 16 patients dying of disease manifested recrudescence within twelve months and were dead in eighteen months.

A large number of inferior hypopharyngeal carcinomata involving the pyriform fossa and the posterior pharyngeal wall are of such a size that the endolarynx and glottis are free of disease; these lesions have

TABLE 3

Death with disease	10	3
Absolute survival	43/64 (67%)	9/17 (53%)
Tumor survival	52/64 (81%)	13/17 (77%)

been resected by subtotal laryngopharyngectomy and radical neck dissection. The results are shown in Tables 5 and 6.

An equivalent result is obtained by subtotal resection in this group of 29% absolute survival rate. The fact that the results approximate those obtained by total sacrifice of the larynx supports the use of conservation techniques.

There were eight patients who had recurrence of their carcinoma. There were five cervical recurrences and two primary recurrences, and one patient developed pulmonary metastases. Only one of these recurrences developed later than eighteen months postoperatively. This developed four years postoperatively in a patient who had multiple oropharyngeal carcinomas, and it may have represented another primary lesion.

Superior Hypopharynx

Until the present time most lesions in this area have been treated almost solely by irradiation. The results have been generally poor and have approximated 20% or less.²

We feel that involvement of the pre-epiglottic space as well as cervical lymph node metastases are factors in irradiation failure.

Therefore since 1958 we have performed an extended supraglottic subtotal laryngectomy on these cases with the results depicted in Tables 7 and 8.

In the group of failures 15 of 19 patients have died of persistent disease, nine with persistence in the head and neck. Six had disseminated metastases. In this group all the patients dying of persistence were dead

within eighteen months.

The two-year survival rate is therefore a valuable figure as to the number of patients likely to develop persistent hypopharyngeal disease.

In the hypopharyngeal groups there was a combined survival rate of 40% of 62 patients in a disease which previously carried a high mortality.

Combined Therapy

The objective of combined therapy, preoperative irradiation followed by surgery, is to improve survivals and cure rates. Naturally, where the cure rates are very high the demonstration of the value of irradiation would be difficult. Thus preoperative irradiation is not indicated for any glottic lesion where surgery is contemplated. The value of preoperative irradiation for epiglottic carcinomas is questioned. There are exceptions, however: a very large supraglottic cancer encroaching upon pharyngeal structures of the larynx, (aryepiglottic fold and aryte-

noid) or the presence of palpable adenopathy.

The cause of failure of surgery for hypopharyngeal carcinoma is often due to persistent disease. Because of the relatively high risk of recrudescence we have elected to treat patients with this disease with preoperative doses of irradiation followed by immediate surgery. By this mode of therapy we hope to reduce the incidence of implantation and metastases produced at the time of surgery.

The dose of irradiation is 2000-3000 rads over two to three weeks. We have chosen this dose in an effort to avoid an increase in surgical complications and still obtain an effective morbidity of the majority of tumor cells.

This series is too recent to discuss cure rates; however, analysis of the failures is valuable. As noted in a series involving patients treated by surgery alone, recrudescent disease has uniformly been manifest within the first twelve months of risk. Thus far we

Death with disease	19	6
Absolute survival	13/32 (41%)	4/10 (40%)
Tumor survival	13/32 (41%)	4/10 (40%)

have preoperatively irradiated 60 patients with inferior hypopharyngeal carcinoma and 19 patients with superior hypopharyngeal carcinoma. These patients have all had the surgical procedure performed which was indicated prior to any irradiation. In the inferior hypopharyngeal group only 12 of 60 (20%) patients have developed persistence in the first twelve months compared with 24 of 73 (33%) in the non-irradiated group. Of the 19 patients with superior hypopharyngeal carcinoma, three of 19 (16%) have developed persistence in the first twelve months compared with nine of 23 (40%) in the non-irradiated group.

Tentatively it appears that planned preoperative irradiation and immediate surgery will be a valuable adjunct in the treatment of carcinomata of the laryngopharynx in which there is a relatively high risk of recrudescence.

Summary

Surgical therapy for carcinomata of the larynx and laryngopharynx has produced encouraging results. Early glottic cancer, that is, a small cancer of the membranous cord can be cured by full irradiation. Larger lesions involving the anterior commissure

and vocal process or extending subglottically for 5 mm. should have a hemilaryngectomy. Total laryngectomy is not indicated in these lesions.

Subtotal surgical therapy of carcinoma of the laryngopharynx and supraglottis has produced encouraging results. These may be improved further by planning preoperative irradiation and surgery. Surgical treatment of this disease does not always entail total laryngectomy as was previously the situation. As many as 50% of patients seen in our office with this disease were treated by larynx-conserving operations with the gratifying result of cancer cure and preservation of normal phonation and deglutition.

He cures most in whom most have faith. — Galen

Could it be
something
more than
growing
old that
“gets her
down”?

Mild mood depression, poor appetite, little interest in the present or future. Does this picture mean that she's giving in to functional fatigue?

When functional fatigue is part of her problem, Alertonic can help counteract accompanying apathy and inertia. It helps lift mood, stimulate appetite, and establish new interest in daily life.

Pleasant-tasting Alertonic combines pipradrol hydrochloride—a gentle cerebral stimulant—with an excellent vitamin and mineral formula, in a satisfying 15% alcohol vehicle.

Especially in the aging patient, nothing fosters confidence and a sense of well-being better than your own personal warmth, understanding, and encouragement. Between visits, however, your prescription for Alertonic can help keep your patient from giving in to functional fatigue.

Adequate dosage is important: Prescribe Alertonic—one tablespoonful t.i.d., 30 minutes before meals...tastes best chilled.

And for your patient's sake, prescribe Alertonic in the convenient, economical one-pint bottle.

Available only on prescription
Alertonic®

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%, pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B₁) (10 MDR*), 10 mg.; riboflavin (vitamin B₂) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B₆), 1 mg.; niacinamide (5 MDR), 50 mg.; choline,† 100 mg.; inositol,† 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.

†The need for these substances in human nutrition has not been established.

Indications: 1. Functional fatigue such as that often associated with: a depressing experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive compulsive states.

Side effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical

facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

The Injured Larynx

ALDEN H. MILLER, M.D.*
Los Angeles, California

SPEED AND MORE speed is the essence of both the causation and the management of injuries to the larynx. Faster and faster automobiles, higher speed limits, more high-speed freeways result in more and more anterior neck injuries by striking steering wheels and dashboards. Speed and increased efficiency in rendering emergency care either at the site of an accident or at a close-by hospital also result in more laryngeal trauma being brought to the laryngologist. And some speed is needed in the successful care of these patients.

Restoration of the normal functions of the larynx after injury will be the most complete and take the shortest time if the patient is seen immediately by the laryngologist. Many times a tracheotomy has already been performed either at the site of the injury or with the patient's first medical care. This does not change the dictum that the laryngologist should start his treatment immediately unless there is an exceptional reason for delay.

It is important to determine two things in the patient whose anterior neck has been struck by the steering wheel, the dashboard, or other objects such as a fist, a cable, a stick, a knife, or a bullet. These two are: first, has the airway been compromised or obstructed; second, has there been a tear in the lining of either the air passages or the food passages?

Diagnosis

External examination of the neck, indirect mirror examination, X-ray examination, direct laryngoscopy, tracheoscopy, and upper esophagoscopy in that order are needed to make a diagnosis and determine management.

Subcutaneous Emphysema

First, one should look and feel for subcutaneous air or crepitus.

*Clinical Professor of Otorhinolaryngology-Surgery and Head of Otorhinolaryngology Department, University of Southern California School of Medicine.

Generalized crepitus of the neck usually means a rather large tear of the trachea or possibly lower parts of the respiratory system. Localized or only spot emphysema usually means a small tear or may denote a rupture of just a ventricle. A tear of one false cord has resulted in air over one wing of the thyroid cartilage, and tears of the hypopharynx have produced subcutaneous air in small lateral neck areas. Tears of the larynx tend to give small areas of subcutaneous emphysema, while tears of the trachea seem to result in more wide-spread emphysema.

The Larynx

Loss of the thyroid notch or the prominence of the "Adam's apple" in the male usually means that the laryngeal cartilages have been fractured and/or displaced posteriorly. If it cannot be seen or felt in the female the same possibility is indicated. Sometimes actual mobility, displacement, crepitus of fractured cartilage, dislocation, and point tenderness can be palpated.

Dyspnea, stridor, cough, voice changes, and expectoration of bloody, frothy mucus should be looked for. The patient must be questioned about difficult or painful swallowing. This latter usually means a tear of the hypopharynx.

Laryngoscopy

Indirect examination with the laryngeal mirror comes next. Pooling of saliva with or without fresh blood usually means a posterior hypopharyngeal tear. However, a vertical tear of the posterior surface of the cricoid eminence has also had the same result. Pooling of saliva without blood could mean a tear of the cricopharyngeal area or its immediate sub-area. Foreshortening of the anteroposterior diameter of the glottis means dislocation of one or both arytenoids from the cricoid cartilage. Usually there may be swelling and sometimes hematoma of the arytenoids or false cords, paralysis or restriction of the movements of the larynx, or dislocations of the structures of the larynx; or an arytenoid may be tilted medially as well as posteriorly, concealing the

true cords and glottis. Recently a tilting inwards of the entire supra-glottic structures of one side, that is the aryepiglottic fold, the false cord, and the arytenoid, was most prominent.

X-ray Examination

Lateral X rays of the neck should be obtained in order to identify the presence of air in the soft tissue spaces. Air in the retropharyngeal or precervical vertebral area usually means a tear of the hypopharynx, pyriform sinus, cricopharyngeus or uppermost esophagus. Air resulting from tracheal or laryngeal tears is more widespread and is anteriorly, laterally or posteriorly placed. Air in the root of the neck, mediastinum or pleural cavities usually denotes tracheal or lower tears. Good X rays may also demonstrate airway or structural deviation of the larynx.

Direct Laryngoscopy

The first direct laryngoscopy should always be done with basal and topical anesthesia so that the presence or absence of laryngeal paralysis can be noted. A second direct examination can be done with general anesthesia if necessary. The laryngoscope proves or adds to the laryngeal mirror examination. Often in injuries, the epiglottis must be elevated to reveal the trauma to glottic structures. Tears of the pyriform sinuses and cricoid area are often seen only when the larynx is lifted forwards.

Equally important and necessary is the passage of the largest bronchoscope. This will be therapeutic as well as diagnostic. Tears of the sub-glottic area and the trachea all the way to the carina should be searched for. Small tears will probably be treated conservatively, but large tears, sometimes completely circumferential, may mean separation of one tracheal ring from another or the separation of the first tracheal ring from the cricoid. These latter will necessitate open surgery and suturing of the torn parts. Again, it must be stressed that any air in the neck calls for complete examination of the entire trachea by means of the bronchoscope. Not only is the passage of the

bronchoscope diagnostic, but it also constitutes the first, the most important, and sometimes the only treatment that is needed. The bronchoscope is used to reduce, elevate, or "iron out" the fractured and dislocated parts of the laryngeal cartilages. Sometimes the immediate improvement following this procedure can be seen with the withdrawal of the scope which has lengthened the anteroposterior diameter of the larynx and produced a more normal topography of the parts. Sometimes, as in the recent instance of the tilting inwards of all of one side of the larynx, a second "ironing out" under general anesthesia has resulted in very adequate restoration of the airway.

Finally, an upper esophagoscope should be used to inspect the posterior wall of the oropharynx, the hypopharynx, the pyriform sinuses, the postcricoid area, the cricopharyngeal area and the upper half of the esophagus.

Treatment

"Ironing Out" the Trachea

Many times the initial "ironing out" is all that is needed in treatment; and often following it the tracheotomy tube that may have been used in the emergency can be removed in a few days. One should usually wait a week and then determine on the basis of repeated indirect mirror examinations whether subsequent "ironing out" with the bronchoscope, or possibly with the passage of rigid metal laryngeal dilators, is needed.

Indwelling Plastic Tube

If these repeated dilations do not result in a good airway, it is then advisable to place an indwelling section of plastic tubing for continuous dilation and reduction of dislocation until subsequent healing results in an adequate airway. A section of a size 9 or 10 Portex tube or endotracheal tube is ideal.

These have the rigidity needed and do not seem to result in any irritation or infection of soft tissues while being dilated and held in place. These sections are introduced into the trachea through the tracheotomy opening and their lower bevelled end is tied to the especially fenestrated and ringed silver

tracheotomy tubes. Such sections are usually left in place a minimum of three or four weeks and can be replaced as well as removed through the tracheotomy opening in gradually increasing sizes if necessary.

Open Operation

If the initial examination reveals a large or circumferential tear of the trachea, or if separation between tracheal rings or from the cricoid cartilage is demonstrated, an open operation must be done. At this time all torn areas are sutured, an indwelling section should always be placed, and the specially fenestrated and ringed tracheotomy tube should be used.

Nasogastric Feeding Tube

If this first examination demonstrated a tear of the hypopharynx, a nasal feeding tube should be placed and left in place for all feedings for usually one week. In one patient a tiny tear of the posterior wall of the uppermost esophagus was also successfully treated with just an indwelling nasal feeding tube. But larger and lower esophageal tears have had to be repaired by an external surgical approach.

For the ideal management the above treatment is that which should be instituted when the patient is seen in the first few hours or days after his injury. Of course, an exception would be that patient who has other injuries to the skull or brain, or other fractures which preclude direct examination and treatment. Mediastinal and pleural air might be another contraindication, as would other internal injuries that would make such a procedure hazardous. The above method of treatment presupposes a closed injury with intact skin. These are the circumstances usually encountered. If skin and soft tissues are torn and the cartilages fractured or dislocated, these tissues may be replaced and sutured through the external wound before its closure. The indwelling plastic tube must always be used to maintain any open reduction or suture.

Late Treatment

Sometimes the patient with laryngeal trauma is not seen by the laryngologist for

two or three weeks following the injury. In such an instance the first step in treatment is a direct laryngoscopy and passing of the largest possible bronchoscope in an attempt to "iron out" any dislocation. This has been successful in a few cases as late as three weeks after the injury. If it is not successful or the patient comes to the otolaryngologist much later, an indwelling section should be placed. Usually there is a tracheotomy and its opening is enlarged upwards as high as the lower border of the cricoid cartilage in order to allow inspection, the carving out of scar tissue and the placing of the largest possible section. Skin grafting of such a dissected out area is not indicated unless there is very large or completely circumferential baring of submucosal tissues.

A tear of just the hypopharynx or pyriform sinuses or cricopharyngeal area has been indicated when air was noted by crepitus or X-ray examination to be only in the posterior pharyngeal or prevertebral areas. These patients have no embarrassment of their airway and need only the placing of a nasopharyngeal feeding tube. Lower tears of the upper esophagus have been missed because all attention had been focused upon the fractured and dislocated larynx which had necessitated a tracheotomy. In some of these patients attention was directed to the esophagus because of great pain, dysphagia

and evidence that food was entering the tracheobronchial tree.

In a few patients paralysis of abduction has persisted even after the laryngeal and subglottic tracheal airway was reestablished. This has necessitated arytenoidectomies or arytenoidopexies.

Summary

It is stressed that the otolaryngologist, if possible, will do a direct examination and institute treatment when he first sees the patient. An attempt should be made with the largest possible bronchoscope to "iron out" any dislocation of the larynx. The use of indwelling laryngeal sections will maintain the realignment of fractured parts. The demonstration of large tracheal tears or cartilaginous separation necessitates open surgery with repair and placement of sections. Painful and difficult swallowing with pooling of saliva, blood, and drooling usually denotes a tear of the hypopharynx or pyriform sinuses. The use of an indwelling nasal feeding tube may be needed for these patients. Most tears of the esophagus necessitate open surgery and repair. The use of continuous dilation and realignment of fractured and dislocated cartilage by the use of the indwelling sections has obviated the use of other procedures, such as open reduction and sleeve resections.

Types of Obesity

Pleasingly Plump

A nice, convenient classification of obesity might be first, just mildly obese, which should refer to the pleasingly plump individual who does not stick out too much here and there, and who may realize that it is better to prepare and prevent than to repair and repent.

The Stout Type

The second degree of obesity could be termed the stout or corpulent type who bulges fore and aft. He usually wheezes and puffs, and is forever trying to impress his audience with his light-footedness in spite of his flat-footedness.

As Viewed from the Mirror

And last, there is the really fat individual, whose chins are a part of his chest, and if he does happen to move, he flows. He has given up trying to be thinner even next year, and has also given up the inspection of his hidden bodily acres that he can view only with a mirror.*

Bamadex® Sequels®

DEXTRO-AMPHETAMINE SULFATE (15 mg.) SUSTAINED RELEASE CAPSULES
WITH MEPROBAMATE (300 mg.)

**to help establish
a new dietary pattern**

Contraindications: Dextro-amphetamine sulfate: in hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness.

Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Venereal Disease A Serious National Problem, Says AMA

Venereal disease is spreading so rapidly that it now represents this nation's most urgent communicable disease problem.

VD is hitting particularly hard among teenagers and young adults, according to the American Medical Association.

The venereal diseases are infecting about two Americans a minute—3,000 a day, or 1,100,000 a year. Cases of infectious syphilis have almost tripled in this country in the past five years. More than a million

new cases of gonorrhea are developing annually.

VD can blind, cripple, and even kill.

The ravages of venereal diseases are all needless tragedy, says the AMA, because both syphilis and gonorrhea can be avoided. If contracted, they can be cured by prompt medical treatment.

The cure for both diseases—penicillin—has been available since 1943. Any family physician or public health clinic can administer

prompt treatment.

Venereal disease is caused by intimate personal contact.

Complacency, ignorance, and a free-and-easy attitude toward moral standards are partly responsible for the spread of VD; the increasing use of alcohol, especially among young people, also plays a role.

Authorities believe, however, that thousands of young people simply aren't aware of the dangers of VD. Once infected, they are complacent about treatment.

One of the first signs of syphilis may be a painless, ulcerating sore. Gonorrhea produces inflammation of the genital and urinary tracts, and a discharge of pus.

A person may contract syphilis and be unaware that he has the disease. After the first symptoms, the germs may remain hidden in the body for as long as 20 years before any damage is discovered. Then the person may become crippled, develop heart disease, blood vessel disease, blindness, or show mental symptoms. Even death may result from this hidden stage of syphilis.

If left untreated, gonorrhea may be responsible for arthritis, endocarditis, sterility, and blindness.

If a person suspects he may have contracted venereal disease, he should go to a physician immediately.

VD should be treated promptly by a physician.

Endolaryngeal Removal of Benign Tumors

FRANCIS E. LEJEUNE, SR., M.D.*
New Orleans, Louisiana

ENDOLARYNGEAL REMOVAL OF benign tumors of the larynx may be accomplished by indirect or direct laryngoscopy. Considerable skill is required to remove small tumors, such as polyps, papillomas, or granulomas, from the vocal cords by the indirect method. Not only is thorough cocainization of the hypopharynx and larynx necessary, but for successful removal the patient must be cooperative and tolerant. For this reason, relatively few tumors of the vocal cords are removed by indirect laryngoscopy.

Direct Laryngoscopy

Direct laryngoscopy offers possibilities of greater success in the removal of tumors of the larynx. Endolaryngeal surgical procedures entail use of a laryngoscope, which permits a direct and satisfactory approach to the larynx. Several types of laryngoscopes are available for direct exposure of the larynx. Undoubtedly, the most popular type in this country is the Jackson laryngoscope or one of its modifications. It provides a beautiful view of the larynx and usually requires only local anesthesia. With this laryngoscope the larynx is approached through an opening about the size of a dime. Surgical removal of a tumor from the vocal cords requires use of a forceps and only one hand. With one-handed surgical removal of these tumors, however, it is always possible to tear or strip the vocal cord mucosa.

Suspension Laryngoscopy

Another method, which is used by relatively few laryngologists, is suspension laryngoscopy. It offers an unexcelled approach to the larynx through a wide open mouth and permits use of both hands to remove the growth. It is our method of choice for endolaryngeal surgical procedures.

Suspension laryngoscopy is best done with

*Department of Otorhinolaryngology, Ochsner Clinic, New Orleans.

the patient anesthetized with sodium pentothal and curare as described by Welborn.¹ After the patient is completely anesthetized, the suspension laryngoscope is introduced into the mouth, and the larynx is exposed to direct vision. By sitting at the head of the table and projecting a beam of light into the mouth, the surgeon can view the hypopharynx and larynx satisfactorily in most patients. With a laryngeal spatula the vocal cords can be retracted for better visualization of the tumor, and palpation can be carried out as desired.

Retraction of the ventricular band provides better visualization of the ventricular area. If a polyp or small papilloma is to be removed from the edge of the cord, the tumor is grasped with a Yankhauer-Little forceps and, while slight traction is made to the opposite side, the tumor is excised by sharp dissection with a laryngeal knife in either the right or the left hand, depending on the location of the tumor. We have found that a #11 Bard-Parker blade sharpened on both edges gives excellent results.

With suspension laryngoscopy the approach to the larynx is limited only by the size of the mouth. We have found through the years that the larynx is much easier to expose and visualize in edentulous patients.

Laryngeal Polyps

In our experience the most frequent growths in the larynx and on the vocal cords are polyps. These are not true tumors but are inflammatory reactions and in their early stages may disappear spontaneously. At times, however, they attain considerable size. When persistent, they must be removed surgically. If removed accurately and with as little trauma to the vocal cord as possible, little or no impairment of vocal function will result. This is also true of other types of benign growths.

Papillomas of Childhood

The most frequent tumors of the larynx found in little children are vocal nodules and multiple papillomas. Unless severe hoarseness is present, vocal nodules in children are not removed until the child has reached the age when cooperation is assured.

Multiple papillomas of the larynx are the most feared tumors in children. These growths seem to have a predilection for the underprivileged child.

Because of the excellent exposure, wide approach to the larynx, and use of both hands, suspension laryngoscopy offers the best means for removal of this type of growth. Pinching or scalping off the papillomas with the Yankhauer-Little forceps, caution being exercised not to bite into the substance of the cord or mucosa of the larynx, has given us the best results. If this technic is followed, it is rewarding to see, when papillomas no longer recur, vocal cords that appear quite normal in spite of multiple operations for removal of these growths.

Papillomas after Puberty

It is generally believed that multiple papillomas disappear about the age of puberty; but this is not always true, since we have seen adults who stated that they had had these growths since childhood. Multiple papillomas may develop in adult life and recur in a manner similar to the way they do in children. An interesting observation was disappearance of papillomas from the vocal cords and larynx in three patients during pregnancy. Shortly after termination of the pregnancy the papillomas recurred. From a research point of view this observation is significant.

Contact Ulcer Granulomas

Aside from specific granulomas, two types of granulomas are occasionally seen in the larynx. Contact ulcers, which always occur at the vocal process, may be unilateral or bilateral and are due to overuse of the voice. The mucosa covering the vocal process is extremely thin, and when traumatized by the opposite process, becomes ulcerated; infection follows and granulating tissue soon appears. With the aid of suspension laryngoscopy the posterior portion of the larynx is easily exposed to direct vision, and the granulating tissue is removed with forceps, care being exercised not to injure the arytenoid cartilage. Vocal rest is imperative.

Although the granulations recur with considerable frequency requiring removal, I have never seen a case that eventually did not clear up.

Intubation Anesthesia

Progress in medicine is responsible for another type of granuloma which began to be encountered shortly after introduction of intubation anesthesia. Granulomas occasionally develop after long intubation anesthesia. They may be unilateral or bilateral. The most common site is the vocal process, but occasionally they develop in the middle third of the vocal cord. Unlike granulomas occurring in conjunction with contact ulcers, intubation granulomas as a rule do not recur after removal.

Polypoid Degeneration

Bilateral polypoid degeneration of the vocal cords is characterized by extensive polypoid tissue on the contact surface of the cords extending from the anterior commissure and ending abruptly at the vocal process. It develops from constant irritation, possibly owing to excessive talking and smoking. The polypoid tissue is soft and baggy and at times so extensive as to cause over-

riding of each cord with resultant increased hoarseness and mild dyspnea. Because of faint transparency of the tissue it is often possible to see the edge of the true vocal cord through the polypoid tissue. Though extremely friable, this tissue can be grasped with forceps and, with slight traction to the opposite side, excised along the edge of the cord with a sharp laryngeal knife just short of the anterior commissure. The opposite cord is treated in the same manner, care being exercised to leave a small amount of polypoid tissue at the anterior commissure. This, of course, is done to prevent formation of a web at the anterior commissure.

Benign Tumors

Other benign tumors of the larynx, such as fibromas, hematomas, cysts, and angiomas, are removed by the same technic as previously described. If bleeding persists after removal of any of these tumors, the bleeding vessel is electrocoagulated with the Cameron pistol grip combination of suction and cautery. Cysts of the epiglottis, occasionally extremely large, are dissected free and, after removal, the mucosa is approximated and sutured effectively to cover the raw areas. This type of suturing is possible only with use of suspension laryngoscopy.

Surgery in the Bible

This is my covenant, which ye shall keep, between me and you and thy seed after thee; Every man child among you shall be circumcised.

And ye shall circumcise the flesh of your foreskin; and it shall be a token of the covenant betwixt me and you.

And Abraham took Ishmael his son, and all that were born in his house, and all that were bought with his money, every male among the men of Abraham's house; and circumcised the flesh of their foreskin in the self-same day, as God had said unto him.

And Abraham was ninety years old and nine, when he was circumcised in the flesh of his foreskin.

Genesis 17:10, 10, 11; 22, 23.

Derivatively Speaking

ARTERY is derived from the two Greek words *aer* (air) and *terrein* (to keep), because the Greeks thought that the arteries like the windpipe contained only air. Though Galen later found that the arteries were not empty but conveyed blood, the name artery persisted.

Cinderella Story

It's a modern Cinderella story. Almost every woman who develops uterine cancer can be cured—if the cancer is discovered early and treated promptly. The "Pap" test—a simple, painless examination which your doctor can make in his office—can detect uterine cancer in this early, curable stage.

Make the "Pap" test part of your annual health checkup. Fight cancer with a checkup—and a check, sent to **CANCER**, c/o Postmaster.

AMERICAN CANCER SOCIETY

The Role of the Respiratory Mucosa

In
Health
and
Disease

A. C. HILDING, M.D., Ph.D.*
Duluth, Minnesota

THE RESPIRATORY MUCOSA, together with its mucous blanket is in effect a vital organ which, fortunately, has recently been receiving some measure of the attention which its importance warrants. This has not always been the case.

Respiratory Mucosa

The respiratory mucosa can be said to line the entire tract from the vestibule of the nose to the alveoli, including the eustachian tube, the middle ear, the mastoid, and the sinuses. It is usually thought of as being ciliated and so it *is*, in the posterior two thirds of the nose, eustachian tube, sinuses, and tracheobronchial tree, at least as far as the terminal bronchioles, and sometimes into the respiratory bronchioles. It is by no means a uniform structure, however, but varies greatly according to its exposure to air flow. In the anterior portion of the nose, where it is exposed to unconditioned air entering the anterior nares, it is of the thick, squamous type. The air enters with a high velocity in the form of jets directed more up than back. Other areas that are normally covered by squamous epithelium include the pharynx, portions of the epiglottis, the ary-epiglottic folds, and the vocal cords. In addition, in otherwise normal people, squamous islands frequently occur in the tracheobronchial tree. Non-ciliated also is the mucosa of the middle ear, the mastoid, and the portion of the lungs distal to the respiratory bronchioles. In these areas the epithelium flattens out until it approaches endothelium in appearance. In fact, it becomes so thin in the alveoli that for a time its very existence was questioned. Recalling that the alveoli are said to contain an area as large as one or two tennis courts, and including the lining of these areas as respiratory mu-

*From the Research Laboratory, St. Luke's Hospital, Duluth, Minnesota. Work supported by United States Public Health Service Research Grant No. GM 09603-03; work sponsored and housed by St. Luke's Hospital, Duluth, Minnesota.

cosa, it follows that by far the greatest portion of the respiratory mucosa is non-ciliated.

Mucous Blanket

Throughout the whole tract, upper and lower, the mucosa is overlaid by an intact blanket or lining of mucus that is completely changed many times a day. This system is something like an escalator or belt conveyor, the cilia supplying the motive power, and the mucous blanket being the conveyor. This mucous blanket is referred to as the ciliary stream.

The Nose

In the nose the ciliary stream moves very slowly over the squamous areas in the anterior third (1 or 2 mm./hr.); in the rest of the nose it moves relatively fast (about 10 mm./min.), and it leaves the nose posteriorly on the lateral wall of the pharynx. The whole drainage from the lateral wall of the nose forms a rather narrow stream which divides around the eustachian orifice. It is here that the ciliated epithelium ceases, the mucosa becomes squamous in form, and the swallowing mechanism takes over the drainage. In the lower tract the mucous blanket is thinner (less deep) in the small bronchi than in the trachea, and becomes shallow to the vanishing point in the alveoli. But even here there is some mucin in the secretion, and it is thought that drainage is accomplished slowly by means of traction, with respiratory movements perhaps playing a part.

The Alveoli

Another physiologic mechanism in the alveoli, the surfactant, keeps the alveoli open and the lung uniformly expanded, even though the alveoli, saccules, and atria are of different sizes and shapes. This surface-active material is thought to be a phospholipid and has the property of changing surface tension in such a way that, as the alveoli are distended in inspiration, the surface tension increases, whereas, as the alveoli grow smaller in expiration, the surface tension decreases, until it practically reaches

zero. If the alveoli were lined by a water layer, the reverse would be true: the surface tension would decrease as the alveoli expanded, and increase so greatly as they contracted, that they would be likely to collapse, causing atelectasis.

Tracheobronchial Tree

The ciliary stream in the tracheobronchial tree might be likened to an upside-down river. In this picture, the alveolar areas (one or two tennis courts of them) represent the meadows in the drainage system; the water there is not easily visible and moves slowly toward the river. The respiratory and terminal bronchioles would correspond to the rivulets in which small streams of water can be seen flowing slowly, later joining to make brooks, and, eventually, the river. So the bronchioles unite into larger bronchi, and eventually the trachea (our river). Both in the geographic river and in the ciliary stream, the stream-bed grows progressively narrower and the depth and volume of the flow progressively greater. In the short distance from the periphery of the lungs to the bifurcation, the stream-bed of the ciliary flow narrows from meters to 5 cm. — the circumference of the trachea.

Obstructions

Just as the geographic river encounters obstructions in the form of sand bars and islands in its course, so the ciliary stream meets obstructions. The opening of each tributary bronchus becomes an obstructing island around which the mucus must flow. Thus, at the upstream margin of each bronchial opening, the mucous blanket must cease its axial flow, split, and change direction to go around the opening. Recalling that there is a similar blanket coming from the tributary bronchus, which also must split on the carina where the two bronchi join, one would readily understand that here is a four-way split in the blanket, with probably some slowing of flow. When squamous islands occur, they are apt to be found on the crests of carinas. These and squamous islands located elsewhere may not stop the flow, because the blanket is dragged across

by adjacent cilia, but there is likely some slowing at such points. Again, at the squamous-covered vocal cords, the ciliary stream meets obstruction, and the blanket coming up the anterior wall of the trachea must cease its axial progress, as at a jettie. The mucous blanket must split at the anterior commissure, as the direction of flow changes from axial to transversely backward, as it follows the cord margin.

Changes with Development of Disease

This then is a brief description, as it is found in health, of the barrier-mechanism that stands between us and that part of our environment that we breathe. When disease develops as a result of its exposure, secretions may be increased a hundred-fold, the thickness of the mucosa enormously increased, and its character entirely changed.

Eighteen times a minute we breathe air that varies widely as to temperature, humidity, and air ion content. This barrier-mechanism must not only prepare the air for reception in the lungs but also conduct it there. The air may contain a wide variety of community and industrial pollutants, odors — pleasant and otherwise, dust — both organic and inorganic, bacteria, viruses, and pollens. The nose warms and humidifies the incoming air very effectually, but dust filtration there is not complete.

Deposition

Deposition of particulate matter results from the interplay of a number of forces: inertia, velocity, air friction, gravity, and diffusion. Practically all particles 10 microns or more in diameter, most 5 microns, and a substantial percentage of those measuring 2 to 5 microns in diameter are deposited in the nose. This deposition is due largely to velocity, inertia, and gravity. Below 2 microns, these forces are not effective. Neither is diffusion, which does not take over until the particle size is less than half a micron. Thus between 0.5 micron and 2 microns, deposition is at its lowest point (20 to 30 per cent) and filtration least effective. Below

0.5 micron, deposition increases again, and all particles less than 0.1 micron in diameter are deposited by diffusion. In addition to size, the shape of particles and specific gravity have a bearing.*

Particles deposited in the alveoli are removed through "sump pores" and taken into the lymphatic system (with or without phagocytic action), or they may be picked up by "dust cells", macrophages, in the alveoli. These cells find their way upward to the terminal bronchioles, where they either disintegrate, dropping their load of particulate matter, or are carried out intact in the mucous blanket.

Fate of Deposited Particles

The fate of the particle itself, the damage it does to the cell, and the reactions of the cellular tissue depend upon the nature of the particle. Some may be dissolved and absorbed quickly (almost as quickly as some gases) and have an immediate general effect. Some inert ones may be removed completely and harmlessly, and others which dissolve slowly may affect the underlying cells more or less severely as they move along, depending upon the intimacy and duration of the contact.

Carcinogenesis

Contact time is increased where the ciliary stream is slowed. This is thought to be the key to the location and genesis of malignancy in the tract. Nasopharyngeal carcinoma arises high on the lateral wall of the pharynx, where the ciliary stream coming from the nose meets squamous epithelium in Rosenmüller's fossa. This is thought to explain the high incidence of this type of carcinoma in Chinese people. They are said to have certain fibrous bands, which span Rosenmüller's fossa and are not found in Europeans. In the lower tract, squamous islands in the bronchi, especially on the crests of carinas, and the vocal cords are points of slowing. Squamous cell carcinoma of the larynx is prone to occur in the anterior portions of the vocal cords, and the most active part of such carcinomas is the anterior portion.

*For those who are interested in this subject, a comprehensive text, *Pulmonary Deposition and Retention of Inhaled Aerosols* has been written by Hatch and Gross (Academic Press, New York).

Bacteria and Viruses

If the deposited particulate matter consists of bacteria and viruses, the effect upon the underlying cells and the tissue reaction will depend upon the nature of the organism. The viruses of the common cold, of which there are 30 to 40, and of influenza are common ones which attack the respiratory mucosa. Typically, they invade the mature columnar cells, forming inclusion bodies in or near the nucleus, after which these cells exfoliate. Such exfoliation may reduce the epithelium to a single layer of replacement cells next to the basement membrane. From these cells the epithelium must be rebuilt and, during this process, the epithelium is probably quite susceptible to infection by bacteria.

Minimal Surface Trauma and Epithelial Repair

The exfoliation of the epithelium was imitated, to a degree, in experiments in which the surface cells were subjected to minimal mechanical damage. In these experiments, it took from five to seven days for the epithelium to rebuild. The last to be replaced were the cilia. These develop from centrioles, the same centrioles which take part in mitoses, but, instead of replicating themselves once, as in mitosis, to form two cells, they replicate themselves scores of times, to form scores of cilia on a single cell.

Pollens

Pollens may penetrate the epithelium with their well known effect. In this condition, however, there is little or no exfoliation.*

Industrial Fumes

The effect of industrial fumes depends upon their natures and their solubilities.

Under certain conditions, the mucociliary system may be so completely destroyed that a fatal outcome is likely. This occurs in chronic disease such as severe asthma, in acute infections like laryngotracheobronchitis, and in chemical destruction, as from war gases or other inhaled chemicals. Under

such circumstances, the patient may die from mucociliary insufficiency unless special measures are taken to get air into the lungs and to get secretions removed, until the epithelium can begin to repair.

Genetic Disease

Not all diseases of the respiratory mucosa are due to inhaled noxious materials or local infections. Some are due to general metabolic disease; others are genetically determined, such as hyaline membrane disease and cystic fibrosis.

Cigarette Smoke

Cigarette smoke is a unique form of air pollution which, among those who smoke cigarettes, far exceeds all commercial and community pollution combined. This form is characterized as "personal pollution." It is purposefully and willfully produced. Unlike other forms of pollution, it does not pass through the nose to be partially filtered. (In experimental animals, it has been found that the nose filters out at least a third of the chloroform-soluble constituents of cigarette smoke.) It is taken directly into the mouth in a form so unbelievably dense that one cannot appreciate it unless he actually watches the business end of a cigarette, as it delivers its charge, under the conditions of time and pressures used by smokers in taking their "drags." Typically, a cigarette smoker takes about 35 cc. of the dense smoke into his mouth and then, in the pharynx, feeds it into the next incoming flow of inspired air, some 500 cc. Most smokers exhale again, before it is all deposited. Roughly half is retained. There are, however, wide variations in the habits of smokers, that is, the manner in which smokers handle the charge after receiving it in the mouth. Some small number puff it out again, as do typical pipe smokers, in which case it does not enter the respiratory tract at all and its damaging effects are slight. Others open the mouth and take a big breath through the mouth, thus driving the whole undiluted charge right down to the alveoli, then hold the breath for a few seconds, until it all deposits. Five seconds is usually

*Acute and chronic infection and allergy are discussed elsewhere in this issue.

enough to accomplish complete deposition of visible smoke. There are all variations of habit between these two extremes.

The resulting effect upon the respiratory tract depends not only upon the temperature of the burning coal at the end of the cigarette, but upon "how much and how often."

The different chemical compounds that have been found in cigarette smoke are so numerous that it takes pages to list them. The mucociliary mechanism does exceedingly well in clearing out a large part of these smoke materials. However, there are many compounds with which it cannot cope and some which it handles indifferently well. Some of the components of the gaseous phase are very quickly absorbed and quickly exert an effect upon the whole body, for instance, nicotine and carbon monoxide. Much of the tar is apparently removed by ciliary action, but some of the components, nevertheless, injure the epithelium and cause chronic trouble. Among smokers, squamous areas are very much more common than among non-smokers, and these seem to occur commonly at the four-way split in the mucous blanket, on the carinas. At this point also, radioactive polonium, contained in cigarette smoke, accumulates in quantities far above what it does on the smooth walls of the bronchi. Lung cancer commonly occurs in the medium-sized bronchi, supposedly beginning in squamous islands. More than three quarters of the lung cancers are found among cigarette smokers. Cancer of the vocal cords, as described earlier, is likewise prone to occur in cigarette smokers.

Among other effects, cigarette smoke is ciliostatic. There are a number of compounds in both the tar and the gaseous phases which have the effect of slowing or stopping ciliary action. This hampers lung clearance. Eventually some areas, presumably those which get the brunt of smoke effects, take refuge in a squamous form of epithelium. This does not necessarily mean that all such areas will develop malignant change, but it seems fairly clear that a developing malignancy goes through this stage. The steps of the change from well-ciliated, columnar epithelium to squamous epithelium have not been spelled out. Be that as it may, chronic conditions develop, characterized by increased production of viscid secretion, invasion by bacteria, bronchitis, and emphysema, with all the museum of pathologic conditions found in those two related diseases. In this country we are experiencing a very rapid rise in the incidence of chronic bronchitis and emphysema, very largely among smokers. The most effective therapy seems to be cessation of smoking.

Conclusion

To discuss adequately the subject of this paper, one would produce enough volumes to fill a library, but perhaps these few comments may serve to emphasize the importance of the respiratory mucosa. Fortunately, its role is currently being studied more than ever before. Even the lay press knowledgeably discusses emphysema, ciliostasis, and hyaline membrane disease. As to advertisers — one might think that some live on self-diagnosed sinusitis!

A Pioneer Greek Surgeon

Antyllus (2nd Century) was the creator of arterial surgery, and was the first to distinguish aneurysm caused by pathological dilatation and aneurysm forming after trauma of the artery. When he treated a circumscribed distention of the arterial wall by ligating the aneurysm above and below the pulsating sac, followed by opening the aneurysm and evacuating its bloody contents, he projected his name to the present time, for the method of Antyllus is still pictured in the textbooks and defined in the dictionaries.*

Pharyngeal and Esophageal Dysfunction

The Diagnosis

JOHN A. KIRCHNER, M.D.*
New Haven, Connecticut

THE PHARYNX and esophagus form a channel for transporting ingesta from the mouth to the stomach. Since the pharynx also admits inspired air on its way to the larynx and lung, breathing is reflexly arrested for a moment during swallowing. The airway is further protected by the laryngeal sphincter mechanism and by the valleculae and pyriform sinuses which act as temporary reservoirs for residual ingesta after the first swallow is completed. Fluids are rapidly moved from the mouth to the esophagus by the "squirt mechanism" produced by the upward pressure of the tongue against the soft palate and faucial arches. The pharyngeal walls have little or no effect on the passage of thin liquids into the esophagus. Solids are conveyed through the pharynx by a contraction wave which passes from the mouth down through the muscular walls of the pharynx and merges with the esophageal peristaltic wave which follows.

Pathophysiology

Disorders of deglutition can result from muscular dysfunction anywhere along the oral-pharyngeal-esophageal tract. The mechanism of the disorder usually becomes evident as the patient reports his symptoms, although he may not complain primarily of dysphagia. For example, excessive mucus and cough may be due to laryngeal flooding from a paralyzed, dilated pyriform sinus, or from a pharyngeal diverticulum. Usually, however, the patient can localize the level of the disorder if the physician helps with a few questions directed at the oral, pharyngeal and esophageal stages of swallowing.

Patient Evaluation

History

Is there any difficulty in moving food or liquid from the front of the mouth to the

*Professor of Otolaryngology, Yale University, School of Medicine.

throat? The oral stage of deglutition depends on normal function of the tongue, soft palate and suprahyoid muscles.

Do liquids escape from the nose during swallowing? This would indicate a weakness of the soft palate or superior constrictor muscle. Do fluids cause coughing or choking? Paresis of one or both sides of the hypopharynx can produce these symptoms. They are often accompanied by hoarseness or vocal weakness as a result of ipsilateral vocal cord paralysis.

Is there a gurgling sound in the throat? This suggests diverticulum of the hypopharynx, as would a report of regurgitating food eaten some time previously. A diverticulum may also cause coughing spells during the night, when the patient is recumbent and the pharyngeal muscles relaxed.

Is it necessary to perform several attempts at swallowing before food descends into the esophagus? This is sometimes an early manifestation of myasthenia gravis.

Do solid foods get caught somewhere between the throat and the stomach? The patient can usually point to the level of obstruction. This may be due to stricture, neoplasm, pressure from adjacent masses (substernal thyroid, aortic aneurysm or cardiac enlargement) or neuromuscular disorders such as achalasia.

One should ask whether pain is present, whether it is related to intake of food or fluids, and whether it is referred to the ear or neck.

Recent weight loss is common with organic disorders of deglutition, but absent in globus hystericus, a common complaint among tense young women. The choking sensation in this condition does not produce coughing or aspiration, nor does it interfere with swallowing food. Careful inquiry into the patient's way of life usually reveals several possible sources of emotional tension.

Clinical Examination

Physical examination of the patient with dysphagia should begin with an assessment of the patient's voice and speech as he relates his symptoms. Dysarthria or hypernasality should indicate the need for careful

examination of the structures supplied by the cranial nerves, especially nine through twelve. The patient with a recent vocal weakness or hoarseness should be asked to cough. Vocal cord paralysis often makes coughing impossible.

Palpation of the neck may reveal an enlarged, low-lying thyroid gland as a cause of the choking sensation or dysphagia. Deviation of the larynx or trachea from the midline may occur in either paralysis of the constrictor muscles or an enlarging soft tissue mass in the hypopharynx. Digital pressure against the posterolateral aspects of the cricoid ring may disclose moderate tenderness of the cricopharyngeus muscle in globus hystericus.

Inspection of the neck during performance of Valsalva maneuver may identify a bulging pharyngocele or laryngocele, or a dropping forward of the larynx in case of weakness of the supporting constrictor muscles.

Auscultation is occasionally helpful in identifying a pulsion diverticulum.

The intra-oral examination may reveal weakness of the tongue, soft palate or pharyngeal walls. Deviation of the uvula during phonation usually indicates a neurological deficit of the vagus nerve, as does an asymmetrical movement of the posterior pharyngeal wall.

Inspection of the pharynx by mirror is usually the most revealing part of the physical examination. It may show saliva lying puddled in one pyriform sinus, indicating paresis of the inferior constrictor muscle, usually due to a high lesion of the vagus nerve trunk or nucleus ambiguus. In such cases the vocal cord of the same side is usually paralyzed and lies in a partly abducted position. Saliva can sometimes be seen spilling over from the pyriform sinus into the larynx.

Saliva lying in both valleculae and in both pyriform sinuses is often seen in pseudobulbar palsy or in other disorders of the bulbar nuclei.

Indirect Laryngoscopy

Mirror examination should include at least a quick look at the vocal cords. Rotation of

the glottic chink is often seen in unilateral vagal paralysis, the posterior commissure being displaced toward the side of the paralysis. A difference in position of the two arytenoid cartilages sometimes identifies a unilateral paralysis of the vagus or the recurrent laryngeal nerve, as does a failure of one vocal cord to move briskly or at all. Remarkably enough, these deviations from the normal laryngeal appearance may also be produced by carcinoma of the pyriform sinus or the post-cricoid area. Tumors in these two areas are often beyond the view of the laryngeal mirror and must be found on radiological or endoscopic examination.

X-Ray Examination

A careful radiological examination is prob-

ably the most important single measure in the evaluation of pharyngeal or esophageal disorders. The passage of a barium suspension through the pharynx and esophagus can be observed on an image intensifier and recorded on motion picture film or video tape.

A thin barium suspension passes rapidly through the normal pharynx and esophagus, leaving no residue. A thick suspension is moved along more slowly by the oral and pharyngeal musculature until it is taken by the esophageal peristaltic wave and carried to the stomach. The action is filmed in the anteroposterior and lateral views, with the patient upright. If paresis is suspected, the examination is repeated with the patient in the supine position. The thick barium mixture coats the walls of the mouth and

Figure — Sixty-eight-year-old man with three-week history of hoarseness and dysphagia. Left vocal cord paralyzed. Saliva pooled in left pyriform sinus. Frequent spells of coughing.

Film on left demonstrates the pattern which was initially interpreted as a soft-tissue mass in right hypopharynx (outlined by arrows). Valsalva maneuver on right film shows dilatation of the left pyriform sinus (arrow), indicating paresis of the left inferior constrictor muscle and inability of the left pyriform sinus to empty itself.

Cinefluorography showed that both pyriform sinuses filled completely and evenly during the passage of the barium suspension. This would not occur in the presence of a tumor in this area.

Residual saliva, pooled in the left pyriform sinus, spilled over from time to time into the larynx and produced spells of coughing.

During the following few months, progressive atrophy of the muscles of the neck, shoulders, mandible and limbs occurred. A diagnosis of amyotrophic lateral sclerosis was made before the patient died.

pharynx, allowing easier identification of masses, diverticula, ulcers and areas of asymmetry.

Study of the pharynx should include a swallow with the head turned to the right, and to the left. Turning the head to one side directs the barium into the opposite pyriform sinus, demonstrating its patency and freedom from tumor. Since some people use one pyriform sinus exclusively when swallowing small amounts, a large mouthful of the barium mixture should be given.

Valsalva Maneuver

Another useful technique in examining the pharynx is to have the patient perform the Valsalva maneuver after the pharynx has been coated with barium. This consists of a forced expiratory effort against a closed mouth and nose, and may show the outlines of a mass in the pharynx, or it may demonstrate ballooning of the atonic side in unilateral pharyngoplegia (Figure).

The esophagus is similarly examined with the barium suspension for retained fluid contents; dilatation (as with achalasia* or stric-

ture); rigidity and lack of peristaltic contractions (scleroderma); tertiary contractions (purposeless and nonpropulsive, seen in the aged); areas of extrinsic pressure, intrinsic masses, fibrous ring or hiatus hernia at the cardiac end, and other abnormalities.

Direct Laryngoscopy

Endoscopic examination of the pharynx and esophagus allows more precise visualization or biopsy of areas which are inaccessible by mirror examination. These areas include the pyriform sinuses, the retro-cricoid area of the hypopharynx, and the esophagus itself.

A diagnostic technique which has gained favor in recent years is the measurement of pressures developed within the pharynx and esophagus during the act of swallowing. The patient simply swallows the end of a small triple-lumen polyethylene tube which is filled with water and attached at its upper end to three pressure transducers and a direct writing recorder. Pressure patterns characteristic of normal peristalsis, diffuse spasm, achalasia, scleroderma and similar disorders can be recognized.

Sickle Cell Anemia — Genesis

At one conference a case of sickle cell anemia in a child of Italian parentage was shown. A discussion of sickle cell anemia in people who live in the countries bordering the Mediterranean sea followed. Dr. Schick pointed out that, after all, Africa is not very far distant from Italy. The pediatric resident said, "Yes, the family had lived in Sicily but there had been no contact with the Negroes, except possibly one day a year, when the circus came to town." Dr. Schick replied tersely. "One day is enough."*

Ten Commandments For Patients

1. Select your doctor carefully.
2. Don't desert him if you find him satisfactory.
3. Ask him questions.
4. Follow his prescriptions.
5. Don't cheat him.
6. Don't expect witchcraft.
7. See him while you are healthy.
8. Assist him as a partner.
9. Keep your own health file.
10. Respect his time and work.

— Martin Gumpert, M.D., *You and Your Doctor*, Bobbs-Merrill, 1952.

|| Tracheotomy

ROBERT E. PRIEST, M.D.*
Minneapolis, Minnesota

TRACHEOTOMY WAS first described just after the beginning of the Christian era; however, the increased prevalence of diphtheria in France in the first quarter of the 19th Century was responsible for the final and convincing demonstration of the possibilities of tracheotomy by Bretonneau and Trouseau. Before the 19th Century, tracheotomy was contemplated only when suffocation was imminent.

In 1546 Brassavola, an Italian physician, described opening the trachea of a boy who was nearly dead from an "abscess in the windpipe." This seems to be the first recorded successful case.

Part of the account of the first tracheotomy performed in Great Britain by George Martine of St. Andrews in 1730 states: "Upon the Subject I should not have had so much to say if this elegant Method of rescuing one from imminent Danger, and the most difficult kind of Death, had not been ordinarily described more from Theory than from Practice, and if Surgeons had been half as bold as to assist Nature in such an Extremity as they are officious to disturb her regular and salutary steps."

The technique of tracheotomy evolved slowly. The first surgeons who performed this operation were afraid to incise cartilage because it was known to heal slowly. They used a transverse incision in skin and trachea.

Tracheotomy tubes were straight and short at first (Fabricius, 1619) and were so illustrated as late as 1795 (Latta's "Surgery"). Casserius (1561-1616) suggested a curved tube with holes in all directions. Sanctorius (1561-1636) advised a straight trochar such as is used in tapping a hydrocele. Martine (1730) was certainly the first to mention a double walled tube, but he does not say that he used it.

*Clinical Professor of Otolaryngology, University of Minnesota Medical School.

Use in Bulbar Polio

Until 1930 tracheotomy was reserved for cases of respiratory obstruction at or above the level of the larynx, but Wilson, in 1932, and Davidson, in 1936, suggested tracheotomy for the relief of respiratory insufficiency due to the bulbar form of poliomyelitis, according to Cawthorne. About this time tracheotomy was suggested as an alternative to repeated bronchoscopy for the removal of secretions in acute laryngotracheobronchitis in children. Galloway, in 1943 and 1947, advocated tracheotomy in various childhood respiratory diseases including bulbar poliomyelitis.

In 1947 Priest, Boies, and Goltz summarized their experiences with tracheotomy in patients with bulbar poliomyelitis treated at the University of Minnesota Hospitals and the Minneapolis General Hospital during the 1946 epidemic.

As a result of this experience, they said: "We believe that tracheotomy has an important place in the treatment of bulbar poliomyelitis. In certain patients, we think it is a life-saving procedure. There is reluctance on the part of some physicians to accept tracheotomy as a useful adjunct in the treatment of poliomyelitis. Any physician whose experience with bulbar poliomyelitis encompasses only a few cases may question the need for tracheotomy. However, an epidemic in which several hundred bulbar cases occur produces a considerable number which meet the criteria for tracheotomy as outlined in this paper."

Five years after the 1947 publication, Priest, Boies, Goltz, Younger, and Koller undertook to review the world's literature to assess the opinions expressed therein concerning tracheotomy in bulbar poliomyelitis. About twenty-six papers on tracheotomy in bulbar poliomyelitis had been published since 1947, representing all shades of medical opinion. Some criticism was truly sharp; but it is of interest that the bitterest critics had not themselves used the method. However, the preponderance of opinion favored the method.

A large poliomyelitis epidemic in Denmark finally convinced the medical world that

tracheotomy could be a life-saving measure in respiratory obstruction arising from any part of the respiratory tract.

The tendency for more and more tracheotomies for respiratory emergencies other than the traditional one of laryngeal obstruction is well illustrated in the Table, made up from figures quoted by Nelson (1958).

Quoting Cawthorne further:

"The extended use of intratracheal anesthesia and in particular the use of closed-circuit machines made the anesthetists appreciate the potential danger of dead space air, particularly when the breathing was shallow. From this has come the realization that, in the shallow respiration of profound unconsciousness, the reduction of the dead space air from 150 cc. to 50 cc. by means of tracheostomy may in itself be life saving.

"Finally, the introduction by anesthetists of the cuffed intratracheal tube, which effectively isolates the lower respiratory tract from the digestive tract and at the same time allows for positive pressure respiration, has solved the problem of 'inhalation pneumonia' and has rendered the iron lung almost obsolete; and there can be few, if any, of those who have had to cope with patients in iron lungs who will regret this.

"The stimulus for this last step came from Denmark when, in 1952, they were struck by a serious epidemic of poliomyelitis with many cases of respiratory paralysis and not enough iron lungs to go around. They had to improvise and, by means of tracheostomy with cuffed tubes and by using teams of medical students to operate manually the positive pressure apparatus, many lives were saved. This led to the development of the mechanical positive pressure breathing machine."

Present Indications for Tracheotomy

Recently, trauma to the head, face, neck,

TABLE

	For Laryngeal Obstruction	For Other Causes Of Respiratory Insufficiency
1940	98%	2%
1954	53%	47%
1958	48%	52%

and chest has provided many indications for tracheotomy. Acute injuries of rather severe degree are becoming more common in our modern civilization with its rapid transportation.

Head Injuries

Tracheotomy is a useful procedure in head injuries with cerebral concussion, even though the face and neck are not injured. Pooling of secretion in the pharynx may occur, and aspiration of this secretion or of vomitus may follow. The use of tracheotomy to permit frequent and adequate cleansing of the lower respiratory tree has grown steadily in recent years.

Facial and Neck Trauma

Jaw fractures, injuries to the front of the neck with edema of the pharynx, and fracture and edema of the larynx make it necessary to provide an airway by opening the trachea below the point of injury.

Chest Injuries

During the past few years, the use of tracheotomy in the treatment of chest injuries has become more and more widespread. The purpose of tracheotomy in chest injury is twofold. Cleansing the lower respiratory tree by suction is probably the most important reason for doing tracheotomy in chest injuries. A second indication occurs in the so-called "flail chest." Here a large segment of the chest wall "floats," and there is paradoxical motion on respiration. When the patient breathes in, the flail segment of the chest goes in instead of out, because

it is no longer anchored to the rest of the chest wall. Positive pressure can be applied during the inspiratory phase of respiration to provide stabilization, or at least partial stabilization of the flail segment of the chest. This reduces pain and also increases respiratory efficiency.

Edema and Secretional Obstruction

Tracheotomy for relief of secretional obstruction in unconscious patients is not confined to head injury cases. It is useful in central nervous system vascular accidents, poisonings, botulism, and drug overdosage. Tracheotomy in burns may be necessary because of aspiration of hot gases which cause edema of the larynx. Of course, tracheotomy does nothing to overcome the primary disease *per se*; but it removes one deleterious factor from the patient's course and hence helps him to overcome the primary disease.

Conclusions

Tracheotomy was first performed in 1546 A.D., but until 1930 it was used only when suffocation from airway obstruction above or in the larynx existed. Then its value in overcoming secretional obstruction was recognized. Since then, its usefulness in bulbar poliomyelitis, head injury, burns, drug and microbial poisonings, chest injury, as well as in laryngeal and pharyngeal obstruction, has become apparent. The operation described by Fabricius of Aquapendente (1537-1619) as "the scandal of surgery" has now assumed a respected place in the surgeon's therapeutic arsenal.

Foreign Body Problems

The Management of

PAUL G. BUNKER, M.D.*
Aberdeen, South Dakota

A COMPENDIUM on the subject, "Management of Foreign Body Problems," would be too exhaustive for this article; consequently it will be limited to those points of importance for the doctor who does not do endoscopy. These points are particularly important since foreign-body patients are usually seen first by the family physician, the pediatrician, or the internist. What these doctors *do* or *do not* do is often of life-saving importance in these emergencies.

Many deaths have resulted from unrecognized foreign bodies which are (unless an autopsy is done) usually attributed to coronary attacks. They occur most frequently in edentulous people who do or do not wear their dentures, especially when dining out, and often in combination with excessive drinking. Dr. Roger Haugen has coined the descriptive term "Cafe Coronary" for these cases.

Radiographic Studies

It is of the utmost importance that a foreign body be suspected in every unexplained respiratory difficulty or dysphagia. Adequate x-ray studies will usually establish the diagnosis, even with non-opaque foreign bodies. If a non-opaque foreign body is suspected in the air passages, inspiratory and expiratory films should always be made to show the changes typical of obstructive emphysema — including the hyperventilated lung and depressed diaphragm on the affected side, plus the mediastinal shift to the opposite side.

Complications

If the emphysema is not relieved by bronchoscopic removal of the foreign body, and if death has not ensued, atelectasis, either segmental or massive, will develop. Later, complications such as bronchiectasis, lung abscess, or even empyema can occur.

*Specialist in Otolaryngology and Bronchoesophagology.

If a foreign body is especially irritating, death can occur by a patient literally drowning in his own secretions. Death can also occur from a completely obstructing foreign body such as a large bolus of unchewed meat. A bean can quickly swell to approximately $2\frac{1}{2}$ times its normal size in the bronchial secretions and should be removed without delay. Similarly, a carrot can become macerated and softened into a complete plug. Peanuts may or may not provoke a fulminating reaction. Most peanuts are now eaten in a salted form which renders them less irritating.

Localization

Lateral x-rays should always be made to aid localizing an opaque foreign body. Such a body in the transverse position would be in the esophagus, whereas in the sagittal plane it would be in the larynx or trachea. Sometimes multiple coins will be directly superimposed in the action potential film and will appear as one, but can be clearly demonstrated in a true lateral view. In some cases it is necessary to x-ray all structures from the nasopharynx to the rectum to locate the foreign body. In children, x-rays should be made at $1/60$ of a second to eliminate motion. Do not be misled, however, if x-ray studies are negative.

Contrast Media

Contrast media are useful in locating a bone in the esophagus. My favorite method is to use a cotton pledget saturated in iodized oil. This will usually catch on the bone and, by providing bulk and lubrication, aid in spontaneous passage of the bone into the stomach. If this does not occur, the endoscopist can proceed immediately with the esophagoscopy, and the saturated pledget makes it easier to locate the foreign body. Barium, on the other hand, coats the esophageal wall and interferes with endoscopic visibility.

Symptoms

The most common symptom of a tracheo-bronchial foreign body is a wheeze. The rales are usually coarser and lack the sibilant

quality of a true asthmatic bronchitis. Children who are sick in bed with a respiratory infection or an asthmatic attack have time on their hands and are prone to put foreign bodies into their mouths. The overlapping of symptoms of an inhaled foreign body and the illness itself makes the diagnosis more difficult. A cough is also a common symptom of a foreign body, but the cough reflex fatigues rapidly; therefore the doctor should not be misled into a false sense of security when the cough subsides.

Pain and difficulty in swallowing plus excessive puddling of secretions in the hypopharynx and signs of infection are the most common symptoms of an esophageal foreign body.

Endoscopic Removal

In general, endoscopic removal is the only safe method for removing a foreign body from the esophagus or tracheobronchial tree. Meddlesome treatment is fraught with danger which can convert a simple foreign body into a difficult one, or result in serious complications. The latter occur most often with blind attempts at removal, especially trying to grasp the foreign body with a uterine forceps or to dislodge it with a stomach tube. Most foreign bodies lodge first in the larynx, setting up a violent spasm. If this is allowed to subside without interference, most of these foreign bodies will be coughed out.

Back-Slapping

At this stage, back-slapping will cause the patient to take a deep gasping breath, and the foreign body, if not coughed out, will more frequently be aspirated into the deeper air passages. Only if the patient is obviously dying, as manifested by continued choking and cyanosis, should back-slapping be attempted in a last desperate effort to induce the patient to cough the foreign body out.

Use of Fingers

Reaching into the mouth with a finger to remove a foreign body frequently converts a simple foreign body into a difficult one. When this is attempted the natural

reaction of an infant is to try to swallow the foreign body rather than to expectorate it. If the child is old enough to understand, encourage him to "spit" it out.

Esophageal Foreign Body

In adults with a bone in the esophagus, if the patient is not too uncomfortable, relaxants may be tried in the hope that the cricopharyngeal spasm will relax sufficiently to allow the bone to pass into the stomach. In this fortunate event, the patient should be put on a bulk producing diet and cautioned against taking any laxatives. Morphine still remains the best relaxant for this purpose.

Tracheotomy

A tracheotomy can be of life-saving importance if the foreign body is above the level of the tracheotomy opening. Indrawing of the suprasternal notch on inspiration would suggest this necessity. A large bolus of unchewed meat is the most common foreign body of this kind. Every physician should carry a razor-sharp knife for such an emergency. An emergency opening can be made through the cricothyroid membrane. Later a routine tracheotomy can be done if the need persists.

Proteolytic Enzymes

Proteolytic enzymes, where the foreign body is a large bolus of meat in the lower esophagus, can be useful if used judiciously. However, perforation of the esophagus with ensuing death has occurred from their use. In other patients a severe tracheobronchitis or bronchial pneumonia has occurred from aspiration of the highly irritating secretions resulting from their use. If the foreign body does not pass in four or five hours after giving them, esophagoscopy should be carried out without further delay.

Passage into Stomach

Most foreign bodies that pass into the stomach will pass along spontaneously, so that surgical interference is unnecessary. No laxatives should be given and the stools must be carefully examined for the foreign body. Radiopaque pointed foreign bodies should be followed by daily serial x-rays.

Occasionally a foreign body remains lodged in the fundus of the stomach for days or even weeks. To promote its passage into the intestines I give the child a bulky meal, then hold him up by the heels, thus utilizing gravity to get the foreign body out of the fundus into the main stream of gastric contents. While the child is still in this position, the parents are instructed to massage the abdomen with a pill-rolling motion to promote peristalsis, progressing in a circular manner around the entire abdomen. This is an old-fashioned treatment for atonic constipation. The patient is then placed on his right side for a period of 30 minutes to favor passage of the foreign body through the pylorus. This procedure is repeated after each meal.

Practical Points of Therapy

Do not be lulled into a false sense of security if the secondary infection responds to antibiotic therapy. If a foreign body is present, the infection will promptly return when treatment is discontinued.

Try to send a duplicate of the foreign body with the patient so that the best forceps for grasping it can be pre-determined.

Never give dried bread or crackers to a foreign body patient. This stimulates gastric secretions which can greatly interfere with the esophagoscopy.

Respiratory depressants should never be given if there is marked difficulty in breathing. Death in these cases is usually from exhaustion, and the patients need to conserve all of their strength to continue breathing.

Obstinacy and heat in argument are surest proofs of folly. Is there anything so stubborn, obstinate, disdainful, contemplative, grave, serious, as an ass?

—Montaigne

The Tonsil and Adenoid Problem

JAMES A. DONALDSON, M.D.*
Seattle, Washington

IT IS INDEED ironic that there are no universally accepted indications for adenotonsillectomy — one of the most frequently performed operations in the United States. Approximately one third of the children in the United States have had adenotonsillectomies,¹ but over the last two decades there has been a gradual transition toward conservatism. This is in part a reaction to the previous philosophy that the presence of tonsils and adenoids constituted adequate justification for their removal. Unfortunately, some physicians have just as vehemently decried the procedure for any reason. As with most controversy, the “truth” is probably somewhere between the extremes.

Waldeyer's Ring is lymphoid tissue surrounding the entrance of the respiratory tract consisting of the adenoids (pharyngeal tonsil), the tonsils (palatine), and the lingual tonsils. In keeping with other lymphoid tissue, Waldeyer's Ring increases disproportionately in relative size early in life, coinciding with a period of many bacterial and viral upper respiratory infections. While it has been postulated that the lymphoid tissue of Waldeyer's Ring is important in the development of the immune process, recent thoughts are that any role it plays in the immune mechanism has ended at birth.

Because of the coexistence of frequent upper respiratory infections prior to age six years and large tonsils and adenoids, it has seemed a logical presumption that the large tonsils and adenoids were, at least in part, at fault. Occasional dramatic change in the upper respiratory infection pattern subsequent to adenotonsillectomy, but also at the time in life of natural decreased incidence, lent support to this hypothesis. Because the tonsils and adenoids are usually removed simultaneously, it has

*Professor and Chairman, Department of Otolaryngology, University of Washington, Seattle.

been difficult to assess the contribution, if any, of each procedure.

The Efficacy of Tonsillectomy

McKee² recently has conducted a rather well-controlled experiment into the efficacy of tonsillectomy. Excluded from this study were those patients for whom rather definite indications were present:

1. Peritonsillar abscess
2. Pyrexial tonsillitis accompanied by convulsions or flare-ups of renal or rheumatic disease.
3. Frequent or severe tonsillitis over a period of several years despite continuous antibiotic therapy.

Also excluded from the study by virtue of the fact that it was not considered adequate indication for tonsillectomy were those patients referred for colds, coughs, allergic symptoms and others who had had less than three episodes of probable throat infection with cervical adenitis within the preceding year. In addition, patients were excluded from the study if they were having their surgery for deafness, recurrent or chronic otitis media, or proven sinusitis. The patients selected for the McKee study were those whose symptoms indicated three or more isolated throat infections or acute respiratory infections with cervical adenitis within the previous twelve months. It was felt that in this group some physicians would recommend surgery while others would not. Patients were thereupon randomly allocated on the basis of their hospital number to immediate adenotonsillectomy or deferral for at least two years unless an urgent need subsequently presented itself.

Tonsillectomy

Analysis of these data showed quite well that the best results of the operation were in those patients under five years who had had three or more episodes in the preceding twelve months. By age eight years there was no evidence that tonsillectomy was of any value in reducing recurrent bouts of pharyngotonsillitis, unless there was significant morbidity for at least two years.

Adenotonsillectomy

A subsequent series³ comparing adenotonsillectomy with tonsillectomy alone demonstrated that adenoidectomy alone had no influence on the occurrence of throat disease, that otitis media occurred less frequently after either adenotonsillectomy or adenoidectomy, and that reduction of otitis media is attributable to the adenoidectomy rather than to the tonsillectomy. There were twice as many complications following the operation in the children having adenotonsillectomy as in those having adenoidectomy alone.

The logical conclusion therefore is that there are different indications for adenoidectomy than for tonsillectomy and that it may not be necessary or desirable to combine the two unless indications for each are present.

Adenoidectomy

If an adenoidectomy is indicated and the tonsils are left, what are the chances that a tonsillectomy will subsequently be indicated? An excellent study of this problem was carried out by Young⁴ who studied patients from six to nine years following adenoidectomy alone and found that in the entire series only one in eight subsequently developed an indication for tonsillectomy. Of those children over six who had indications for an adenoidectomy alone, only one in twenty subsequently developed indications for a tonsillectomy. It would seem therefore, unjustified to increase the morbidity and double the incidence of postoperative complications by doing an elective tonsillectomy, in the absence of indications, merely because the child is having an adenoidectomy.

Indications for Surgery

Bearing these findings in mind, the indications for surgery may be considered as follows:

Tonsillectomy

- A. Absolute
Peritonsillar abscess
- B. Relative

High Priority

Pyrexial tonsillitis accompanied by convulsions or flare-ups of renal or rheumatic disease.

Frequent and severe tonsillitis over a period of several years despite continuous antibiotic therapy.

Lesser priority

Three episodes of tonsillitis with cervical adenitis within the past twelve months for children seven or under and three or more bouts of tonsillitis with cervical adenitis per year for at least two years for those over seven years.

Removal of unusually large tonsils when necessary to facilitate an indicated adenoidectomy.

Adenoidectomy

- A. Recurrent acute suppurative otitis media.
- B. Recurrent middle ear effusion or secretory otitis media.
- C. Mouth breathing secondary to obstruction of the nasopharynx with adenoid tissue.

The Nature of Bacterial Invasion

One of the largest areas of confusion has been the differentiation of viral pharyngotonsillitis from bacterial pharyngotonsillitis. A recent study by Evans and Dick⁵ at the University of Wisconsin showed that for a college age population at least 26.3 percent were caused by hemolytic streptococci, 37.8

percent were caused by viruses, and 35.9 percent were of unknown etiology.

It is unfortunately very difficult without cultures to distinguish streptococcal from non-streptococcal infection in that an exudate was common to all of them. It was found, however, that there was a tendency for the white count to be generally higher in streptococcal infections and for the general malaise to be greater in viral infections.

Except for the absolute indication and a few of the high-priority indications for tonsillectomy, the morbidity of the procedure must be compared with the necessity of administering antibiotics for each subsequent bout of tonsillitis. For adenoidectomy, however, one must, in addition, consider the irreparable damage to the tympanic membrane, ossicular chain, and middle ear cavity if the eustachian tubes are blocked over a prolonged period of time or if recurrent bouts of otitis media are permitted.

In addition, prolonged mouth breathing from adenoid blockage of the choanae initiates a habit which is difficult to overcome later.

Conclusion

Adenoidectomy and tonsillectomy are two separate procedures with separate indications. They should be combined only when separate indications exist. Antibiotic therapy for recurrent tonsillitis can many times be substituted for tonsillectomy. Procrastination of an indicated adenoidectomy on the other hand may result in irreparable damage to the patient's hearing.

Disease of the Major Salivary Glands

Classification, Diagnosis and Treatment

THE MAJOR SALIVARY glands can be affected by many pathological disorders. One or more glands may be affected. Primary disease is common. Less common is involvement by encroachment, metastases and local manifestations of constitutional disease. The following broad classifications of diseases must be considered:

1. Inflammatory
2. Endocrine and metabolic
3. Neoplastic
4. Traumatic
5. Cystic

Diagnosis

In order to assist the physician in arriving at a judgment upon which rational and definitive therapy can be based, the following diagnostic procedures are available: history and physical examination, general laboratory studies, salivary cytological studies, smears and cultures, sialometry, roentgenographic studies including sialography, duct probing and cannulization, incisional and excisional biopsy and microscopic tissue examination, and finally, where diagnosis still remains obscure, the patient must be periodically re-examined and re-evaluated.

Inflammatory Disorders

Acute

A common acute inflammatory disease involving one or more major salivary glands is mumps (epidemic parotitis). Another is acute sialdochitis, which can be of viral or bacterial origin. Acute sialadenitis is usually self-limited but can lead to abscess formation. Coalescence is usually slow to develop in the parotid gland due to the dense fascial septa. Sialadenitis from an allergic or drug reaction is frequently multiglandular.

*Professor and Chairman, Department of Otorhinolaryngology,
The University of Michigan Medical School, Ann Arbor.

WALTER P. WORK, M.D.*
Ann Arbor, Michigan

Chronic

Chronic inflammatory disease can conveniently be classified as recurrent or progressive. Chronic recurrent disease includes: recurrent sialadenitis, sialectasis, sialolithiasis and duct or orifice stricture. It is not uncommon for patients with chronic recurrent disorders to have acute exacerbations. Commonly pyogenic bacteria are the organisms which account for the exacerbations and chronicity. If the condition progresses, fibrosis and lymphocytic infiltration develop.

Later, destruction of the ductal and secreting elements of the gland occurs. Chronic progressive disease results from granulomatous lesions, such as tuberculosis, sarcoidosis, mycosis infections and benign lymphoepithelial disease (Mikulicz's disease and Sjogren's syndrome).

Treatment

The treatment of patients with salivary gland disease of inflammatory origin can be medical or surgical or a combination of both. Thus the treatment may vary from conservative medical treatment in patients with mumps to other patients with inflammatory diseases, who might require duct probing, removal of stones and strictures or wide surgical incision or excision. Radiation therapy may be used judiciously, particularly in those patients with early acute sialadenitis.

Metabolic and Endocrine Disorders

The disorders which result from endocrine and metabolic disturbances are usually manifested by hypertrophy, enlargement and change of consistency of the affected gland. One or both parotid glands are involved more frequently than the submandibular or sublingual glands.

Hypertrophy

Benign hypertrophy can occur in patients with thyroid gland dysfunction, in the diabetic, or in some patients with alteration of pituitary-adrenal axis.

Atrophy

On the other hand, benign atrophy of

glandular structures can occur associated with fatty or fibrous atrophy. In these disorders, the parotid glands appear to enlarge. Even though the glandular elements progressively atrophy, replacement by fatty or fibrous tissues accounts for the enlargement.

The parotid gland atrophies are without symptoms and occur in patients with a wide variety of conditions, varying from exogenous obesity to collagen diseases. Menopausal hypertrophies are manifested mostly in the parotid glands. Likewise, in some deficiency states, hypertrophy can occur.

In these patients, treatment is symptomatic and directed for the most part to the constitutional endocrine or metabolic disorder. Rarely is biopsy indicated.

Neoplastic Disorders

Neoplasia of the major salivary glands can be benign or malignant and of fibrous or epithelial tissue origin. Further, neoplasias can be a manifestation of constitutional or metastatic disease and, finally, they can occur as direct encroachment from adjacent neoplastic disease.

Benign Mixed Tumors

In the parotid glands the benign mixed tumors are most common, being present in 60-65% of the cases of primary tumors. They occur with less frequency in the submandibular glands. The prognosis is much more favorable in patients with primary malignancies of the parotid glands than in patients with primary malignancies of the submandibular glands.

Diagnosis

Sialography can be misleading and must be used judiciously in tumor diagnosis. In patients with suspected, highly malignant lesions (primary or otherwise) incisional biopsy may be permitted. As a rule, however, wide surgical excision is the treatment of choice. The facial nerve is preserved whenever feasible. If, by necessity, for acceptable excisional removal of the tumor, the facial nerve must be removed, then suture or grafting should be done, either

as a primary or secondary surgical procedure.

Frozen Section

The surgeon and the pathologist must both be continually cautious of final diagnosis by microscopic examination of tissues prepared by frozen section techniques. It may be more feasible for the surgeon to delay destructive surgery in these patients until permanent tissue sections can be prepared.

"Unclassified Tumors"

In recent years the tumors of the major salivary glands are better understood and the group of so-called "unclassified tumors" is smaller. The cooperative efforts of the surgeon, pathologist, radiologist and internist have all accounted for this by astute clinical diagnosis, by improved surgery and radiation therapy, and by follow-up examinations extending over many years.

Surgical Considerations

In most instances, the benign tumor of fibrous tissue origin should be excised widely. In the parotid gland the facial nerve must be preserved. Patients with primary lymphangiomas, lipomas and neuromas, fall into this category. On the other hand, infants with hemangiomas should be observed for expected disappearance. If the hemangioma enlarges or persists, then surgery is indicated.

Since the malignant tumors of fibrous or supporting tissue origin occur often as a local manifestation of constitutional disease, treatment is often medical in the form of chemotherapy or radiation therapy. In some patients with localized malignancy surgery may be carried out. The facial nerve is usually excised and may or may not be sutured or grafted.

Benign Epithelial Tumors

Benign tumors of epithelial origin occur as the benign mixed, mucoepidermoid "tumors" or adenomas. The benign mixed account for 65% of the primary parotid gland tumors. There are stromal and epithelial varieties. They occur in any portion of the parotid gland and may be

deep or superficial to the facial nerve. Medial extensions of the tumor from the retro-mandibular portion of the parotid or from the tail can enter the parapharyngeal space.

Parotidectomy

In any event, the treatment of choice is parotidectomy with preservation of the facial nerve. Recurrence as a rule is due to inadequate surgery. Patients with benign mixed tumors of the submandibular gland are candidates for surgical excision. Total parotidectomy should be done in patients with mucoepidermoid "tumors."

It is often difficult for the surgeon and the pathologist to determine benignity from either microscopic frozen or permanent tissue examinations. Hence radical surgery is indicated with preservation of the facial nerve. Follow-up examination is most important. Benign adenomas should be excised without facial nerve injury. These lesions include papillary lymphoid cystadenomas (Wharthin's tumor), the acidophilic cell and the serous cell adenomas.

Malignant Epithelial Tumors

Malignant tumors of epithelial primary origin in the parotid gland account for 20-25% of tumors and 30-40% of malignancies in the submandibular glands. Malignancies of the submandibular glands have a poorer prognosis than those of the parotid glands. Primary squamous cell carcinomas may be cornifying, non-cornifying or lymphoepithelial in character.

Treatment

Incisional biopsy may be permitted in some of these patients. Radiation therapy can be the treatment of choice, or it may be indicated following surgical excision. The surgeon must decide whether or not the facial nerve is to be removed. Nerve suture or graft is not contraindicated, even though postsurgical radiation therapy is used. In continuity, block dissection of the neck should be done in patients with neck node metastases. Neck dissection may be indicated as a later operation in other patients.

Patients with malignant tumors of gland

cell origin are often difficult to treat. Surgery varies from excisional parotidectomy with facial nerve preservation to radical excision of the gland with neck dissection, removal of the pinna and partial excision of the temporal bone, hemimandibulectomy and VIIth nerve removal. Radiation therapy is recommended as a follow-up form of post-surgery therapy in some patients.

The capricious nature and the clinical behavior of most of these tumors require years of patient follow-up. At follow-up examinations, the patient must be checked for local recurrence, as well as for metastatic disease.

This group includes patients with adenoid cystic adenocarcinomas, serous cell adenocarcinomas and acidophilic adenocarcinomas. Patients with malignant mucoepidermoid "tumors" require radical excision. Perhaps the group of patients with "unclassified" malignant epithelial gland cell tumors present more problems in diagnosis and treatment for the surgeon, pathologist and radiotherapist than do patients with any other malignancies. This is because these tumors often behave in bizarre fashion.

Traumatic Disorders

The parotid gland may be involved in crushing, lacerating, penetrating or other forms of injury.

Facial Nerve

If injury is recent, it may be the opportune time to repair the facial nerve when severed. The facial nerve electrical stimulator can be used to identify peripheral cut fibers up to three days post injury. The proximal cut ends are identified less readily. Main trunk identification away from the laceration and peripheral dissection may be the surgeon's choice to identify the proximal stumps.

In other patients, the surgeon may iden-

tify a proximal cut stump and trace this posteriorly to the pes annerimus. In this manner, other cut branches may be identified by tracing them distally through the parotid gland.

Serious Injury

In seriously injured patients, choice of priority of treatment often modifies timing of parotid gland and facial nerve repair. If Stensen's duct is lacerated, it should be sutured over a polyethylene tube, anchored with a "stay" suture at the papilla in the buccal cavity. In the surgical exploration of patients with parotid gland injuries, bone fractures must be noted and treated. Likewise, the soft tissues must be debrided, foreign bodies removed and the soft tissues meticulously approximated by suture. If significant trauma occurs to the submandibular gland, it should be removed. Injury occurs less frequently here than in the parotid glands because of the protection of the horizontal ramus of the mandible. Nerve suture or graft of the mandibular division of the facial nerve can be accomplished in some patients. If severed, the lingual nerve should also be sutured.

Cystic Disorders

Cysts of the major salivary glands can follow trauma, stricture, inflammation; or they may occur as a congenital lesion. The parotid gland is most frequently affected. When patients have symptomatic disease, treatment is surgical. In the parotid gland this may mean total parotidectomy with preservation of the facial nerve. This is particularly true when the cysts are multilocular and extensive. In some patients with superimposed, acute inflammation, external incision and drainage should be carried out, followed by wide surgical excision as a secondary procedure when indicated.

Individualism

It would seem that the study of medicine does not always contribute to broadmindedness, as men who choose medicine as a profession are apt to lose rather than gain breadth of perception. It could be said rather that medicine develops individualism.

— Charles Mayo

A Mass in the Neck

The Diagnostic Approach

GEORGE F. REED, M.D.*
Syracuse, New York

THE DIAGNOSIS OF masses in the neck has been the subject of innumerable articles in medical literature. The manifold interest in masses in this portion of the body is easily understood when one recognizes the complexity of highly important structures in this region, the many and varied types of tissue present, and the many opportunities for congenital abnormalities to occur in this area. It is the purpose of this presentation to evaluate the important, present-day, common diagnostic problems relating to neck masses as they affect the lives of the majority of patients encountered with such masses, rather than to recount a complete differential diagnosis.

Midline Neck Masses

With the reader's understanding that this is not an attempt to explore and discuss all causes of neck masses, it is possible to divide them into two main categories; midline and lateral. It is then possible to fairly quickly dispense with midline masses, since these are by and large of thyroid origin, well-known to most physicians and quite easily diagnosed as enlargements of the thyroid lobe, the thyroid isthmus, or developmental abnormalities of thyroid development such as midline aberrant thyroid, thyroglossal duct cyst, etc. With the exception of dermoid cysts, which may appear in or near the midline of the neck, such thyroid abnormalities constitute by far the huge majority of midline masses and present no significant problem of diagnosis.

Lateral Neck Masses

The remaining cervical swellings of diagnostic import are, therefore, composed of the masses appearing in the lateral portion of the neck, the largest number of which (excluding infectious lymphadenitis in chil-

*Professor Chairman of the Department of Otolaryngology, State University of New York, Upstate Medical Center, Syracuse, New York.

dren) constitute metastatic foci from primary malignancies elsewhere in the body. Again, by far the greatest percentage of such metastases is from the area of the head and neck, albeit cervical metastatic nodes may occasionally appear from other primary sources such as the lungs, stomach, pancreas, etc. It should be realized that approximately 80% of lateral neck masses constitute metastatic neoplastic disease, mainly from primaries in the head and neck region.

Benign Lesions

Accordingly, it is important that the primary attention and thinking of the examining physician be centered about this possibility, rather than the rare or esoteric causes of lateral cervical swelling such as branchial cleft cysts, laryngoceles, pharyngeal and esophageal diverticuli, dermoid cysts, sebaceous cysts, cystic hygroma, submaxillary gland enlargement due to ductal obstruction, etc.

Fortunately, these more rare causes of neck masses are accompanied by a history of longer duration, cystic nature on examination, or such other unusual signs and symptoms as to allow the luxury of leisurely study and contemplation of their etiology prior to definitive diagnosis.

Diagnostic Approach

The presence of a firm swelling in the lateral portion of the neck must be considered malignant until proven otherwise. Its nature and origin demand a speedy and definitive diagnosis to insure prompt and proper therapy. All too often the patient's life is dependent upon proper and expeditious evaluation of the cervical mass.

Search for Primary First

One of the most serious mistakes that can be made in diagnosing a mass in the neck is that of proceeding directly to open biopsy. Otolaryngologists and other head and neck surgeons are continually faced with the surgical problems and dire consequences of neck biopsy without a thorough and complete search of the upper respiratory tract for evidence of a primary source of malignancy.

All too often, biopsy of a cervical node is considered the most direct approach to a diagnosis, or a thorough search for a primary site is neglected because of the examiner's inability to adequately examine the many areas wherein a primary carcinoma may lurk.

This is to be decried, since the proper management of most carcinomas of the head and neck, with cervical metastases, entails an en-bloc resection of the primary with a radical neck dissection encompassing the connecting lymphatics in one specimen.

Problems of Open Biopsy

Prior biopsy of the neck metastasis greatly compromises the patient's chance of cure by seeding of the surrounding tissues and by opening lymphatics for further spread of cancer cells. Accordingly, it can be categorically stated that, rather than being the most direct approach for the establishment of diagnosis of a lateral cervical mass, open biopsy should be reserved as the *last* diagnostic procedure in such swellings.

It must be remembered that if a thorough search for a primary source of malignancy does reveal a primary lesion, the preliminary biopsy of cervical nodes not only increases the chances of dissemination of disease in the neck but limits the benefits of neck dissection. Likewise, it makes the resulting neck surgery infinitely more difficult because of biopsy scarring and the necessity of including large areas of skin and subcutaneous tissues in the operative specimen.

Upper Respiratory Tract

From the above considerations it is readily seen that the most important diagnostic measure in the evaluation of a cervical neck mass is that of a complete and thorough examination of the upper respiratory tract in the search for a primary carcinoma.

Nose and Nasopharynx

This search must include a minute examination of the nasopharynx with both the nasopharyngeal mirror and nasopharyngoscope, since lesions in this area are notor-

iously treacherous and may appear as only slight fullnesses of the submucosal tissues or as slight fissures in the nasopharyngeal mucosa. The entire area of the pharynx, mouth, tongue, and floor of the mouth must be examined very carefully, not only by direct visualization, but also by palpation, to detect the firm, deep lesion which may be present within the substance of the tongue or tonsillar tissue, escaping the notice of surface examination.

The interior of the nose must be searched with the nasal speculum and nasopharyngoscope after the mucosa has been satisfactorily shrunk with topical vasoconstrictors. The search for an obscure primary lesion should also involve diagnostic radiographic studies of the sinuses.

Larynx and Hypopharynx

The larynx and hypopharynx must be explored by indirect laryngoscopy with adequate topical anesthesia so that all areas of the larynx, hypopharynx, and pyriform sinuses are satisfactorily visualized. If any of these laryngopharyngeal areas are not completely visualized, the patient should have a direct laryngoscopy before the search is considered complete. Only after such a survey of the upper respiratory tract has been completed, is biopsy of the cervical mass justified.

Needle Biopsy

In the instance where no primary lesion has been found and good pathology facilities are available, it is the author's opinion that needle biopsy is preferable to open biopsy. In the event that the cervical mass is cystic rather than metastatic, this will be elucidated by needle biopsy; and if a mass does represent metastatic carcinoma, this may be verified by needle biopsy with minimal dissemination of tumor cells and the least compromise of subsequent therapy by surgery or radiotherapy.

Open Biopsy

If needle biopsy is inconclusive or if pathology facilities are unavailable for reliable interpretation of needle biopsy mater-

ial, then and only then is open biopsy of cervical masses indicated. When open biopsy is utilized, it should be done through a minimal incision placed within the prospective incision lines of a subsequent radical neck dissection if this becomes necessary.

If a large solid tumor is encountered, biopsy specimens only should be obtained, to minimize the deleterious effect upon a subsequent neck dissection, rather than attempting to remove the mass by local excision. On the other hand, if small lymph nodes are encountered, it is preferable to remove an entire node for biopsy rather than violate its capsule. If a cystic or otherwise obviously benign condition is encountered at the time of biopsy, then of course the operative site can be extended and the lesion removed as definitive treatment.

Frozen Section

In the absence of a known or suspected primary lesion, the reliance on frozen section biopsy in the decision to proceed with radical neck dissection is ill-advised. Permanent sections might indicate lymphoma or other pathology wherein further surgery would be detrimental or might give a clue to repeat a search for a primary locus wherein an en-bloc resection, with the primary, would be of much more benefit than separate resection.

Radical Neck Dissection

In the instance where the patient has had a previously known and treated primary carcinoma in the region of the head and neck, a cervical mass should be approached vigorously. No more than two to three weeks time should be utilized in hoping that the cervical mass is inflammatory. It has been demonstrated that approximately 80% of such cervical nodes in the drainage field of previous head and neck malignancies are, indeed, metastatic.

With this type of odds, one is well justified to proceed with definitive radical neck dissection in the attempt to achieve a maximal chance of cure, rather than be party to further delay or other diagnostic measures. If one feels that there is serious doubt and

wishes to have the support of biopsy confirmation, such biopsy should be done in the operating room with frozen section and preparation to proceed immediately with radical neck dissection. The specimen in this case should include the skin and subcutaneous tissues violated by the biopsy procedure.

Summary

A practical consideration of the diagnosis of masses in the neck indicates that, in adults, such masses usually fall into the category of easily diagnosable midline swellings of thyroid nature or occur in the lateral portions of the neck. Approximately 80% of lateral cervical masses represent metastatic malignancy and, therefore, must

be viewed with alarm and evaluated without undue delay.

Proper evaluation of lateral cervical masses must begin with, and include, a careful and complete examination to detect the slightest aberration indicative of a possible primary malignancy.

Open biopsy is the *last* diagnostic measure to be employed in the evaluation of a cervical mass and must be performed by a surgeon prepared to proceed with definitive removal of a benign lesion if encountered, and with a full understanding and respect for the influence and effect of such biopsy on subsequent total management of the disease process, if the mass be of a malignant nature.

On Diet and Hygiene From Regimen Sanitatis Salernitanum

Eggs newly laid and broths of richest juice
 With ruby wine, increase of strength produce,
 Wheat and milk make flesh, brains and tender cheese,
 Marrow and pork as taste they chance to please.
 Or eggs with art prepared, or honeyed wine;
 Ripe figs and grapes gathered from the vine.

Let air you breathe be sunny, clear and light,
 Free from disease, or cesspool's fetid blight.

From washing after meals two gains arise:
 The hands are cleansed and strengthened are the eyes.
 If thou in health prolonged wouldst ever stay,
 Wash frequently thy hands each passing day.

Goat's milk and camel's, as by all is known,
 Relieve poor mortals in consumption thrown;
 While asses' milk is deemed far more nutritious,
 And e'en beyond all cow's or sheep's officious.
 But should a fever in the system riot,
 Or headache, let the patient shun the diet.

Neurosis does not deny the existence of reality, it merely tries to ignore it: psychosis denies it and tries to substitute something else for it. A reaction which combines features of both these is one we call normal or "healthy"; it denies reality as little as neurosis, but then, like a psychosis, is concerned with effecting a change in it.

Palatal Insufficiency

Correction of

DEAN M. LIERLE, M.D.*
WILLIAM C. HUFFMAN, M.D.*
JEANNE K. SMITH, M.A.*
Iowa City, Iowa

VELOPHARYNGEAL INCOMPETENCE, the inability of a person to speak without noticeable nasality, can result from a variety of conditions. Whatever the etiology the mechanism is essentially the same: inability to close the port between the mouth and the nose. This is true whether the nasality is due to palatal excision for malignancy, paralysis, congenital shortness, cerebral palsy, scarring or cleft palate. The last named condition is by far the most common etiologic factor and further discussion will be limited to it.

Nearly every aspect of cleft palate management is a matter of some controversy. Included in the moot points are the method of management (prosthetic or surgical?), the age at which any contemplated primary surgery should be done, type of surgical repair, efficacy of any type of treatment, need and desirability of secondary surgical procedures and so ad infinitum.

The Use of Prostheses

Except in instances presenting some definite contraindication, most people concerned with palatal clefts prefer surgical repair to prostheses. These dental appliances need to be removed and cleaned several times a day, must be changed in size to keep pace with a child's growth, are subject to breakage, and are certainly of no benefit to the teeth to which they must be attached. However, when definitive surgery cannot be done or when it has failed, prosthetic obturation can be a great boon.¹

Surgical Repair

Surgical repair of a cleft palate is like any other type of surgery in that it does not always produce the desired result, elimination of hypernasality in speech. This is most often due to the fact that so many cleft palates are not only split palates but,

*Department of Otolaryngology and Maxillofacial Surgery.
University of Iowa Hospitals, Iowa City, Iowa.

in addition, are shorter than the non-cleft palate. After repair of the cleft the posterior edge of the short palate is unable to contact the posterior pharyngeal wall when needed in the speech process, and thus permits nasal escape of air. Unfortunate patients who cannot gain velopharyngeal competence after repair of a palate may receive great improvement through intensive speech training by a competent clinician. In many communities a speech clinician is an integral part of the public school system.

There remains a large percentage of cleft palate patients who have hypernasal speech after palate repair and competent speech therapy. There are also many postoperative individuals who have overcome this palatal insufficiency only by developing nares constriction and other facial grimaces. All of these are candidates for further physical management, and again we encounter disagreement in the choice of therapy. Some will be helped a great deal by a dental appliance that lifts the soft palate a few millimeters. Others achieve acceptable speech by resorting to an obturator, an appliance that has a bulb attached to a palatal portion posteriorly and is designed to decrease the size of the port between the oropharynx and the nasopharynx.

Secondary surgical procedures aimed at obviating hypernasal speech are legion and nearly everyone of them has its ardent admirers and bitter detractors. Should the palate be lengthened by one or more of several operations devised for the situation?² Should the posterior pharyngeal wall be brought forward by a reefing procedure³ or by submucosal implantation of a graft?^{4,5} Should the size of the aperture between the soft palate and posterior pharyngeal wall be decreased by lifting a flap from the pharyngeal wall and attaching it to part of the width of the free edge of the soft palate?⁶ Should the flap be lifted and rolled up into a ball without attaching it to the soft palate?⁷

At this point it might be wise to digress from secondary velopharyngeal surgical procedures and return for a short time to a few more considerations concerning primary

palatal repair. There are surgeons who practically never repair a cleft palate without incorporating a lengthening procedure.^{2,11,12} There are some who include the attachment of a pharyngeal flap to the posterior edge of the palate as part of a first operation in order to reduce the number of patients who have poor speech after palatal repair.⁸ Quite a few otologists decry the latter concept as it closes access to the nasopharynx for treatment to alleviate ear disease without detaching the flap.

The Lengthening Procedure

One might well ask why the lengthening procedure and, particularly, the flap attachment should be included in the primary operation only in instances where palatal repair was not expected to produce the desired speech result. The answer is an embarrassing one for all concerned. Most people agree that the prognosis concerning speech before or during palatal repair is almost wholly a matter of conjecture.

The original types of lengthening procedures gave poor results in the hands of many surgeons. This was probably due to the fact that a raw surface was left on the mucoperiosteal flap that was moved backward from the hard palate.⁹ Because the raw area had to heal by secondary intention and scar contraction the palate could not maintain its retroplacement. After this was realized, efforts were made to avoid it by placing a skin graft on the raw surface of the flap.¹⁰ This maneuver prevented contracture and reshortening to some degree but often added another objectionable feature, a foul breath resulting from retained desquamated epithelium on the graft's surface. Recent attempts to avoid these two unhappy results have included posterior movement of mucosa from the floor of the nasal cavity¹¹ or fashioning a turnover flap of palatal mucoperiosteum based on one or both greater palatine neurovascular bundles.¹²

Parents of children with repaired cleft palates and adults who suffer from palatal insufficiency are not often aware that further physical management may offer aston-

ishing speech improvement. Due to this paucity of information among the population with palatal incompetence and among persons who might impart information to them, quite a few cleft palate services hold annual information seminars for physicians, dentists, public school personnel, social workers and speech pathologists.

Discussion

The confusion evident in this presentation is no greater than that which exists among persons who are intimately associated with the management of palatal insufficiency. However, by whatever methods happen to be employed by an individual or institution, a great percentage of persons with velopharyngeal incompetence can achieve socially acceptable speech. It is therefore the responsibility of all the allied professions to pursue the problem to the ultimate attainment of all possible improvement in communicative ability.

Results

Analysis of 123 pharyngeal flap procedures done between 1955 and 1962 revealed

that 83.3% had attained velopharyngeal competence.¹³ An additional 100 patients who have had pharyngeal flaps continue to support this degree of palatal improvement.

The success of the operation appears to depend on the width of the flap and the amount of preoperative movement of the palate and lateral pharyngeal walls. Satisfactory results are less frequent in patients over 15 years of age and in those with defective intelligence. It is usually contraindicated in individuals with chronic middle ear disease, chronic sinusitis, or allergic rhinitis.¹⁴

There are a few complications; among these are hemorrhage, partial or total loss of the flap, atresia, and airway obstruction in young children due to pharyngeal edema.

Conclusions

The only valid assessment of the success of pharyngeal flap procedures involves evaluation of the postoperative potential for velopharyngeal closure. This can be observed in nearly all the cases. Speech status evaluations are relevant only to the degree to which they reflect the potential closure.¹³

Phthisis — from Greek *phthiein* (to decay).

INFLAMMATION: A cellular fight for life

A SYNTEX REPORT based on recently developed hypotheses about topical corticosteroids, including the cellular theories of inflammation by Thomas F. Dougherty, Ph.D., University of Utah.

You are looking at a fibroblast fighting for life. This cell—one of the most common found in connective tissue—has literally been poisoned by cytotoxins released from other cells that have ruptured. Soon, if the abnormal activity of this fibroblast does not cease, it, too, will rupture and die—one more casualty in the inflammatory wave of destruction precipitated by injury.

Until a short time ago no one had ever witnessed such a scene at the cellular level. Now, through advanced cinemicrographic techniques, it is possible to view and photograph the inflammatory process as produced experimentally in living animal tissue. This method permits new insight into the mechanism of inflammation and the role of corticosteroids in therapeutic management. Equally important, these techniques shed new light on factors that may make one corticosteroid more effective than another—factors that can be correlated with other chemical, biologic, and clinical parameters.

Phase-contrast microscopy showing mast cell before injury.

Mast cell (after injury) has broken up and released cytotoxins.

Visual evidence of how corticosteroids influence the inflammatory reaction

Working with phase-contrast cine-micrography on living animal tissue, Doctors Thomas F. Dougherty and David Berliner of the University of Utah College of Medicine have actually filmed cellular events that occur during the inflammatory reaction. This remarkable study* and additional work by these investigators, as well as by others, have established a new theoretical biologic basis for the antiinflammatory effect of the corticosteroids. (It must be noted that other theories, such as the lysosome or so-called "suicide bag" theory, have been postulated, although it is quite likely that there are more similarities than differences among the various theoretical models.)

The inflammatory wave of destruction

In this investigation an injurious injection of gelatin is used to set off an inflammatory reaction in living mouse tissue. What follows is a wave of destructive cellular activity that comprises the inflammatory response to injury. Mast cells (which contain heparin, serotonin and histamine) take up water, swell and rupture, releasing their contents, which are toxic outside the mast cell wall. These toxins, in turn, cause disintegration of other cells (such as fibroblasts) and the release of additional toxic material. Capillaries, too, take up water and leak unformed blood elements, causing edema. And polymorphonuclears, lymphocytes and perithelial cells invade the inflamed site. As a result of all these changes, the cellular environment reaches a state of turmoil.

How corticosteroids change the picture

Corticosteroids appear to virtually stop the abnormal cellular activity that constitutes the inflammatory reaction. This permits the body's natural resources to clear up the inflamed area and repair the damaged tissue. This interpretation is supported by the fact that when the injurious gelatin solution is injected simultaneously with a corticosteroid — Synalar (fluocinolone acetonide) — the inflammatory pattern simply does not develop.

Fibroblast in high state of activity, much distorted.

Mast cells showing effects of corticosteroid action: cells are normal in size, shape and activity.

In summarizing his study Doctor Dougherty states: "...we also feel this work may explain why one corticosteroid helps a patient more rapidly and effectively than another. If it does, it is because one corticosteroid is the fastest, most effective inhibitor of the series of inflammatory events at the tissue level."

*A New View of Corticosteroid Action in Inflammatory Dermatoses, a film based on this study, is now available from your Syntex representative.

How advances in chemical design have achieved greater steroid potency

The chemical modification of corticosteroid molecules from the advent of hydrocortisone to the development of Synalar (fluocinolone acetonide) is a prime example of how biochemists can "design" to increase therapeutic activity and minimize undesirable side actions. Below, for example, we see the important changes that were made in reference to the hydrocortisone molecule to produce fluocinolone acetonide, one of the most active of all topical corticosteroids. As a result, a 0.01% preparation of Synalar (fluocinolone acetonide) has been reported to do the work of a 1% hydrocortisone product containing 100 times more corticosteroid. And it can often do it more effectively.

Hydrocortisone

Fluocinolone Acetonide (Synalar)

- a double bond between carbons 1 and 2
- fluorine substitutions at both the 6- α , and the 9- α positions
- the addition of the acetonide at the 16- α , 17- α positions, thus providing one of the most potent topical corticosteroids available.

How bioassay tests are used to "predict" therapeutic potential

Biologic assays are another tool used by researchers to help establish the relative activity of corticosteroids. To date no single method of assaying corticosteroid activity has emerged as the ideal "yardstick" for predicting therapeutic potential. Taken together, however, these methods have proved useful. When such tests are run on various corticosteroids, a definite order of corticosteroid activity becomes evident. Compounds with the highest order of activity may be expected to merit clinical trial to establish their high therapeutic potential. When assayed by these methods, fluocinolone acetonide (Synalar) emerges as one of the most active topical corticosteroids, milligram for milligram, available for clinical application today.

THE THYMUS INVOLUTION ASSAY¹⁻⁴ is run on adrenalectomized rats. The sizes of the glands are measured, and the degree of involution caused by the steroid is determined as an indication of its potency. In the above photo, the comparative involution of thymus glands achieved with hydrocortisone and Synalar (fluocinolone acetonide) is shown. Untreated controls (A) show normal size. Group B— injected with 1, 2 and 4 mg. of hydrocortisone— show progressively smaller thymuses as does Group C— injected with fluocinolone acetonide— but with only 1/500th the dose of hydrocortisone.

THE ANTIGRANULOMA ASSAY¹⁻⁴ also utilizes adrenalectomized rats. Granulomas are induced by subcutaneous implantation of cotton pellets on either side of the thorax. The degree of granuloma inhibition achieved by a steroid reflects its potency. The above photo shows the inhibition of granuloma formation achieved with hydrocortisone and Synalar (fluocinolone acetonide). Untreated controls (A) show large, red granulomas adhering to the pellets. Group B, receiving hydrocortisone and Group C, receiving fluocinolone acetonide, show little, if any, granuloma formation. Fluocinolone acetonide produced the same effect as hydrocortisone with only 1/500th the dose. This assay, as well as the thymus involution assay, measures systemic rather than topical corticosteroid activity. Nevertheless, results by these methods correlate well with other assays and with the milligram potencies of topical steroids in current clinical use.

Worldwide clinical experience confirms the predictable therapeutic potential of Synalar

It is particularly gratifying that the promise of the advanced chemical design and high order of bioassay activity of Synalar (fluocinolone acetonide) has been confirmed by widespread therapeutic application. Indeed, the impressive clinical response rate of Synalar has been documented in no fewer than 232 papers from 22 countries.

PRESCRIBING INFORMATION

For initiation of therapy: Cream 0.025%, 5 and 15 Gm. tubes, 425 Gm. jars; *for emollient effect:* Ointment 0.025%, 15 Gm. tubes; *for maintenance therapy:* Cream 0.01%, 15 and 45 Gm. tubes, 120 Gm. jars; *for intertriginous or hairy sites:* Solution 0.01%, 20 cc. and 60 cc. plastic squeeze bottles; *for infected inflammatory dermatoses:* Neo-Synalar® Cream (0.025% fluocinolone acetonide, neomycin sulfate, equivalent to 0.35% neomycin base), 5 and 15 Gm. tubes.

CONTRAINDICATIONS: Tuberculous, fungal, and most viral lesions of the skin, (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components. **PRECAUTIONS:** Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for pro-

Flaps and Grafts

In Head and Neck Surgery

GEORGE A. SISSON, M.D.*
Syracuse, New York

A SURGEON WELL trained in treating a specific area should be equally capable of restoring the regional physiology of his patient and, therefore, be completely able to assume responsibility not only for his patient's surgical health but also for his final appearance.

As head and neck surgery, often extensive and radical, continues to attract an increasing number of otolaryngologists, so does the need for greater knowledge and appreciation of the various successful reconstruction techniques become increasingly essential.

The following outline represents a somewhat simplified classification of the more useful grafts and flaps used by otolaryngologists, with examples of their application in the rehabilitation and reconstruction of the head and neck areas:

Free Grafts

Full-Thickness Graft

Full-thickness grafts are usually selected when small to moderate lesions on the dorsum of the nose, cheek or forehead are excised.

Split-Thickness Graft

Split-thickness grafts are used to cover large defects on the face, neck, scalp, intra-oral region and most donor sites when the pedicle grafts are large. They are used also to line pedicles and as temporary donor dressings in areas where large pedicles have been borrowed. In special instances split-thickness grafts are of value when placed over the dura which is easily and often exposed during radical maxillectomies with orbital exenterations and during radical temporal bone resections.

Dermal Grafts

Dermal grafts, the "added protection" grafts, are most valuable when used as cov-

*Clinical Professor of Otolaryngology, State University of New York, Upstate Medical Center, Syracuse.

Fig. 2 — Small pedicle flap from naso-alar fold to cover lateral dorsum of nose.

erings over the carotid complex and the pharyngeal suture line in cases where preoperative radiation has been given.

Composite Grafts

Composite grafts usually taken from ear auricles, provide an effective three-layer covering for defects in the lower lateral nose cartilages (Figures 1-A and 1-B).

Fat Grafts

Fat grafts from the abdomen are used for obliterating frontal sinuses and for the restoration of facial contours.

Bone Grafts

Bone grafts from a rib or iliac crest can improve nose contours and zygomas as well as fill antrums to raise orbital floors when correcting late deformities from orbit blow-out fractures.

Muscle Grafts

Temporalis muscle grafts have long been used successfully to obliterate the mastoid cavity. These are often rotated on pedicles, although they can be and often are put in as free implants.

Fascia Grafts

Fascia grafts are currently used very successfully to repair the drum membrane in reconstructive surgery of the middle ear. Temporalis fasciae are convenient donor sites.

Pedicles

Small Pedicle Grafts

Small pedicles are used most frequently and most successfully.

A full-thickness flap is rotated to close most defects over the cheek, lid, forehead, naso-alar fold (Figure 2), dorsum of the nose, and most defects after the excision of large lip lesions.

A useful variation, "the island flap" (Figures 3-A and 3-B), is rotated from the center of the forehead with the pedicle buried in a tunnel and the flap applied to the dorsum of the nose.

Flap Grafts

Large regional flaps represent one of the

strongest grafts available for resurfacing large areas about the head and neck that are "in trouble" (Figure 4). This "troubled area" could be the result of heavy preoperative radiotherapy, a postoperative infection creating massive salivary fistulae which often are associated with impending carotid hemorrhages; or it could be a large facial defect after an extensive excisional resection to control a bulky primary or recurrent cancer. This type of problem can be corrected only if there is an immediate transfer of large viable tissue to the "troubled area." The most frequently used regional flaps and examples of their application are outlined below. All of these flaps are stronger if delayed once; but more often than not, it is unnecessary to delay, and satisfactory results are obtained from the immediate transfers.

Large chest pedicles, sometimes referred to as "nipple flaps," are used when an immediate transfer to the neck of 200 to 250 square centimeters of virgin tissue is necessary. Because of its length this flap is capable of resurfacing one complete side of the neck with ease and can be rotated so as to resurface a completely exposed carotid. In addition, it can be extended into the floor of the mouth for anastomosis with the portion of the tongue still remaining: usually an effective procedure when the construction of a preliminary pharyngostoma is attempted (Figures 5-A and 5-B). This chest flap may be based laterally from the anterior shoulder on a 10 to 12-centimeter pedicle with its two inferior limbs extending obliquely parallel for 20 to 22 centimeters, so that the nipple on the ipsilateral side is included in the flap. It is prudent upon raising the flap to remove a 2x3-cm. triangular wedge on the medial aspect since this is the weakest area of the flap. After edges of the donor area are undermined, the final defect is closed with a split-thickness graft from the thigh. The transposed nipple in the neck can be removed at a later date under local anesthesia. Although it is possible to raise chest flaps from both sides at the same time, this is rarely necessary. Usually an associated, smaller cervical flap will suffice to complete most

Fig. 3-A — Island flap with vascular pedicle buried in tunnel and full thickness pedicle graft sutured to dorsum of nose.

Fig. 3-B — Midline incision closed by undermining and suturing. (Two weeks post-operative)

Fig. 4 — "Troubled area." Post-surgery and radiation with impending carotid blow out. Resurfaced by large pedicle flap from chest. (Nipple flap)

resurfacing. Care must be taken when raising the large chest flap to preserve the deep blood supply under the superficial pectoralis fascia; the skin and the subcutaneous tissue are taken down to the fascia. The axillary artery with its branches, the thoracoacromio artery and the lateral thoracic artery, together with the deltoid artery provide this type of pedicle with a generous circulation.

A modification of this flap is a smaller medially-based chest pedicle which is transposed superiorly and is useful when resur-

facing the lower central and lateral neck. This pedicle derives its blood supply from the perforating branches of the internal mammary artery and may also be raised without delay as two separate grafts, one from each side of the upper chest; and they may be formed at the same time.

Large cervical flaps, raised from either side of the neck and transposed to midline or lateral defects, are a convenient and effective means of bringing new tissue to large distressed areas. However, if a patient has

Fig. 5-A — Large lateral chest flap (400 sq. cm.) transferred at time of surgery to resurface heavily radiated tissue. Extends to floor of mouth.

Fig. 5-B — Sutured in place to form floor of mouth.

had heavy neck radiation a surgeon cannot always use this type of rotation. Viability becomes apparent once the flap is raised. Often several centimeters of the distal end must be sacrificed to insure good healing; but if there is doubt it would be prudent to abandon this effort and transfer non-radiated tissue from the chest as has been described.

Cervical flaps may be used as a combined

flap by delaying and lining the distal third with a split-thickness graft or by folding the end of the flap over on itself and transferring to the defect at a later date. Combined cervical flaps are most useful when reconstructing large oral-cheek fistulae, closing pharyngeal fistulae and reconstructing defects in the floor of the mouth.

Recently cervical flaps have been used to reconstruct palates after radical maxillary

Fig. 6-A — Immediate repair of palate after radical maxillectomy and exenteration of orbit by long cervical flap.

Planning: cross-hatched area will rotate medially, proximally tubed, skin side in, as it passes under the mandible.

Fig. 6-B — Cervical flap raised.

resections and exenterations of the orbit (Figures 6-A, 6-B, 6-C, 6-D). When this technique is employed, the flap is rotated into the mouth proximally, tubed skin side in, where it passes under the mandible. This procedure or variations of it are used when primary reconstruction of the floor of the mouth either laterally or medially is necessary. When the base of the flap is posterior, it is called the "nape of the neck" flap; and since mutilation of the breast is unnecessary it is particularly useful in females. Since the post-auricular and occipital arteries provide

the vascular strength of this flap, these arteries must not be injured as the flap is raised from a subnuchal pedicle which extends down to the fascia over the trapezius.

Large scalp flaps are frequently used to reconstruct an entire nose as well as other large deficit areas on the face. Smaller defects are resurfaced by utilizing median or laterally based forehead flaps (Figure 7). Care must be taken not to injure the superficial temporal artery since the scalp flaps' luxurious blood supply depends upon it regardless of the adaption selected for use in

Fig. 6-C — Cervical flap passed under mandible.

Fig. 6-D — Completed suturing of flap.

this procedure. The classical "sickle flap" or one of its modifications (Figures 8-A and 8-B) is used most often in these situations.

Any one of these large scalp flaps may be combined with a split-thickness graft when a through-and-through defect is to be reconstructed. In a combined technique the transfer usually is staged or delayed until the under surface of the flap, whether covered by a split graft or a folded end, has healed.

Tubular Grafts

Tube grafts may be single or bi-pedicle and merit reference because of their high reliability when used in difficult recipient areas. This graft, once the "work horse" of reconstruction techniques, is not as popular today because a patient must undergo multiple transfer stages, the final reshaping of the migrated tissue into a desirable result is difficult to achieve and the techniques employing the large regional pedicle grafts are better understood today and preferred.

The single pedicle tube may be fashioned from either the upper anterior chest or the

Fig. 7 — A laterally based forehead flap for resurfacing of 4/5 of upper nose.

Fig. 11-A — Bi-pedicle cervical-acromio tube.

Fig. 11-B — Large donor defect closed using rotated lateral pedicle flap from chest wall.

cervical area. A graft from the cervical area is delayed in the first stage as a short bi-pedicle tube which can conveniently be raised horizontally across the anterior cervical area or the acromioclavicular region if necessary. At the second stage a paddle can be formed and lined for use as a combined graft. This lined paddle (Figure 9) can be rotated into the desired position for reconstruction of a through-and-through defect. Careful planning and patience between stages are necessary if this flap is to be used successfully.

The bi-pedicle tube flap can be raised obliquely across the chest wall as an acromioclavicular (Figures 10-A, 10-B and 10-C) or acromioclavicular tube (Figures 11-A and

11-B). If the patient is obese, careful trimming of fat is necessary when the free edges are tubed, because the contents of the tube should not be subjected to any pressure. If large facial or neck defects are to be reconstructed, two bi-pedicle tubes can be raised at the same time from either side of the chest. If healing is complete after a two-week delay these tubes are transferred in stages to the "troubled area." Multiple stages are usually necessary before the final result is completed. This graft, however, is very strong so that even if a portion of it does not survive in a poor recipient area the remaining tissue is usually sufficient for the reconstruction.

"Our general construction is determined by the fact that we are made of living matter, must accordingly be constantly passing a stream of fresh matter and energy through ourselves if we are to live, and must as constantly be guarding ourselves against danger if we are not to die. About 5 per cent of ourselves consists of a tube with attached chemical factories, for taking in raw materials in the shape of food, and converting it into the form in which it can be absorbed into our real interior. About 2 per cent consists in arrangements — windpipe and lungs — for getting oxygen into our system in order to burn the food materials and liberate energy. About 10 per cent consists of an arrangement for distributing materials all over the body — the blood and lymph, the tubes which hold them and the pump which drives them. Much less than 5 per cent is devoted to dealing with waste materials produced when living substance breaks down in the process of producing energy to keep our machinery going — the kidneys and bladder and, in part, the lungs and skin. Over 40 per cent is machinery for moving us about — our muscles; and nearly 20 per cent is needed to support us and to give the mechanical leverage for our movements — our skeleton and sinews. A relatively tiny fraction is set apart for giving us information about the outer world — our sense organs. And there is about 3 per cent to deal with the difficult business of adjusting our behaviour to what is happening around us. This is the task of the ductless glands, the nerves, the spinal cord and the brain; our conscious feeling and thinking is done by a small part of the brain. Less than 1 per cent of our bodies is set aside for producing the race. The remainder of our body is concerned with special functions like protection, carried out by the skin (which is about 7 per cent of our bulk) and some of the white blood corpuscles; or temperature regulations, carried out by the sweat glands. And nearly 10 per cent of a normal man consists of reserve food stores in the shape of fat."*

Mid Facial Fractures

JEROME A. HILGER, M.D.*
DOUGLAS R. KUSSKE, M.D.**
St. Paul, Minnesota

VISUAL, MANUAL and x-ray examination will determine the best program for mid-facial skeletal repair. The objectives are good nasal function, good dental occlusion, normal ocular fusion, and the best cosmetic result obtainable.

The Nose

The composite of bones and cartilage collectively termed "the nose" leads all skeletal parts in fracture frequency. The superior one third to one half of the projecting portion of the nose is formed by the frontal processes of the maxillae surmounted by the nasal bones, which unite atop the middle ethmoidal plate of the bony septum. This complex may shatter in the manner of an eggshell as a result of central facial third impact (Figure 1). The characteristic front-seat passenger smash into the dashboard produces this injury. The frontal process of the maxilla, if sufficiently sturdy may fracture at the infra-orbital abutment with the malar bone and impact with the lacrimal bone into the ethmoid labyrinth.

The usual athletic injury fracture dislocates the nasal bones from on top the frontal processes of the maxillae; the latter may fracture from the main body of the maxillae as well. In either case, the septal plate of the ethmoid is carried in the direction of displacement. This must be reckoned with in the course of reduction.

Upper Nasal Segment

Injuries of the upper nasal segment are easy to diagnose and delineate by palpation and inspection. X-ray examination is much less informative though perhaps more impressive. Doubt whether fracture has occurred can be resolved by looking and feeling again in a few days when soft tissue swelling has subsided. This delay does not prejudice the final result.

**Clinical Associate Professor of Otolaryngology, University of Minnesota.

Otolaryngology Professional Associates, St. Paul, Minnesota.

Fig. 1 — Comminuted (eggshell) nasoethmoidal fracture.

Fig. 2 — Method of elevation of comminuted naso-maxillary elements and insertion of wire transfixion at the base.

Fig. 3 — Completion of wire transfixion technique for comminuted nasoethmoidal fracture.

Realignment of these fractures can be accomplished by intranasal and external manipulation and molding. General anesthesia is frequently desirable. Usually the fragments maintain reposition without splinting. An external molded dressing is sometimes useful to minimize dorsal edema, which can result in slippage of fragments. In addition, it can produce undesirable thickening due to organization of transudate. A modest intranasal support by a petrolatum gauze strip high in the fornix can be useful to prevent impacted fragments from falling back into the chamber. However, intranasal packing stuffed into the nasal space to counter bleeding is a useless and harmful routine measure.

If comminution is extensive (Figure 1) and manual elevation of fragments will not maintain position with these simple efforts, direct wiring and pinning are necessary. Two 32-gauge steel wires threaded on straight needles are passed through the base of the bony nasal mass (Figure 2). Comminution makes this maneuver easy, or the needle can be drilled through. The wires are threaded through molded lead plates, which are snugged to the nasal skeleton to support an agreeable contour (Figure 3). Incorporation of a sheet of synthetic film draped over the intranasal elevators used to advance the mass as the drill wires are placed at the base will keep the torn mucosal surfaces of the vault separated during healing and prevent adhesive obliteration of the anterior respiratory vault.

Lower Nasal Segment

The lower half of the external nose is frequently injured without upper half fracture. The magnitude of this injury is often overlooked, as most of the distortion is intranasal. Externally there may be no obvious displacement — only swelling and tenderness. A palpating finger must always be run down the nasal dorsum (Figure 4). A soft point immediately caudal to the end of the nasal bones means that cartilaginous septal fracture and dislocation have occurred (Figure 5). Intranasal septal swelling will fill the nasal vestibules, due to a ballooning hematoma between the septal flaps (Figures

6-a and 6-b). Therefore, an early intranasal open reduction of this injury is mandatory (Figure 6-d). Lack of diagnosis and neglect result in external nasal deformity and septal airway obstruction (Figure 6-c). Rhinoplastic surgery for the deformity of neglected upper nasal injury is uniformly satisfactory. Rhinoplastic and septoplastic surgery for correction of lower half injury is always a compromise. Once the dorsal ridge hematoma soft spot absorbs and organizes, the inspiratory vault of the nasal vestibule is forever lowered (Figures 6-c and 7). Though the later plastic correction obliterates the saddle of the dorsum and narrows the accorded septum, it cannot restore the height of the intranasal fornix. Diagnostic x-ray is useless in this injury. The keys to diagnosis are the soft spot in the lower half of the nasal ridge into which the palpating finger falls as it slides down the nasal dorsum and the complete obliteration of the nasal airway by the hematoma between the septal flaps.

Nasal Septum

Septal incision, as for a classic submucous

Fig. 4 — Palpation of the cartilaginous nasal dorsum and caudal end of the septum to identify fracture of the cartilaginous nasal segment.

resection, evacuates the subperichondrial hematoma and exposes the multiple fragments of cartilage. Successive replacement of fragments from dorsum to floor is maintained by mattressing chromic sutures through mucosal flaps and cartilage at each fracture line (Figure 6-d). This restores the anatomic relationship of the quadrilateral fragment jigsaw and binds the mucoperi-

Fig. 5 — Dorsal hematoma "soft spot" denoting fracture dislocation of the cartilaginous septum. The mucosa of the intranasal respiratory vault at the upper lateral-septal cartilage juncture is dissected and ballooned downward into the airway.

Fig. 6-a, b, c and d — (a & b.) Cross section of comminuted fracture of the nasal septum; (c.) Organization in septal disarray with lowering of the respiratory vault; (d.) Open reduction, hematoma aspiration, and mattress realignment of the cartilaginous septum.

Fig. 7 — The relative nasal "hump" resulting from lowering of the cartilaginous dorsum as a result of dislocation and comminution of the septal cartilage.

Fig. 8 — Comminuted fracture dislocation of the cartilaginous septum resulting from blow delivered to the caudal end.

Fig. 9 — Chomic suture transfixion of the cartilaginous septum preparatory to anterior traction — reduction of cartilaginous fracture in Figure 8.

chondrium to the cartilage to preclude post-operative hematoma and position change.

Where the injurious blow has been delivered not at the dorsum but at the caudal end of the nose, lip contusion, sometimes upper incisor tooth and alveolar fracture, and quadrilateral septal cartilaginous and anterior nasal maxillary spine fracture and displacement are not uncommon. The cartilaginous septum is accordioned posteriorward (Figure 8). Palpation of the columellar end shows the absence of firm septal edge (Figure 4). Reduction of the posteriorward accordioning will not maintain without loop suture fixation. This is accomplished by inserting a far posterior septal chomic transfixion suture (Figure 9) which is then brought forward and passed through the vestibular floor skin beneath the spine and into the opposite vestibule, there to be drawn taut to "unpleat" the accordion (Figure 10).

"Central-Third" Fractures of the Face

The pyramid in the center of the middle facial third is comprised of the maxillae, the nasal, lacrimal, and ethmoidal bones. Straight, forceful projection of the face into an unyielding receiver may impact the nasomaxillary mass with or without free fracture of the palatal segment.

Fig. 10 — Closure of suture passed through the nasal vestibular floor to embrace the anterior nasal spine and "unpleat" the accordion fracture of the quadrilateral cartilage.

Advancement techniques by postpalatal hook, intranasal-intraoral grasping forceps, and intranasal elevator can be supplemented by "molding" pressures deep to the inner canthal areas to reform the crushed ethmoid mass. Free segments of the frontal processes of the maxillae can best be retrieved from the nasal space and repositioned by "bimanual" manipulation with the fifth finger deep in the nasal vault and the fingers of the opposite hand along the orbital rim. Precise replacement can be further assured by infraorbital incision in the lower crease of the orbicularis oculi and direct visualization (Figure 11). This allows wire loop fixation at this point — either single or multiple as necessary to complete the reformation of the infra-orbital rim and its union to the nearest solid lateral abutment (Figure 12).

Glabellar Area

In the glabellar area similar incisional view of the nasal root (Figure 11) and direct wire loop can be valuable in fixing the pyramid to the frontal skull base if gaping requires closure (Figure 12). This can be combined with nasal mass transfixion and molding with lateral malleable metal splints as already suggested, when the bony nasal mass is "egg-shelled" (Figure 3).

It is important to disimpact the recessed nasomaxillary mass at the first opportunity. Early fusion occurs. A bulging of the ethmoidal labyrinth and retrocession of this

Fig. 12 — The maintenance of anatomic realignment with permanent wire loop fixation.

Fig. 11 — Incisional access lines providing direct exposure for anatomic reduction and wire loop fixation.

Fig. 13 — The fracture zones of the abutting malar-maxillary complex.

central mass are impossible to correct by later plastic repair. Bony union occurs in a matter of weeks due to the thin plates, extensive periosteal surfaces and rich blood supply.

Cribriform Plate

When this type of fracture includes fracture of the cribriform plate and cerebrospinal fluid leak, early reposition is particularly imperative. The breach in the floor of the anterior cranial fossa will more readily and surely heal and seal if anatomic reposition has been accomplished. If stereoscopic skull films demonstrate a bone fragment displacement and intrusion into the anterior fossa, the facial realignment should be performed in conjunction with intracranial removal of the intruding bone from the floor of the anterior cranial fossa. This latter procedure is accomplished neurosurgically by hairline incision and lowering of the total forehead flap.

Pyramidal Area

Whatever the upper aspect of the pyramidal fracture demands for repositioning and fixation at the intermaxillary level, the teeth must be fixed in occlusion. Arch-bar

application provides a good means. If there is no concurrent mandibular fracture, the versatility of the arch bars allows intermittent use of the intermaxillary elastic binders during the late healing period.

Fractured edentulous maxillae present no occlusion problem whether the mandible does or does not have teeth. Intermaxillary fixation is not necessary. Anatomic reduction and direct fixation can be followed by denture revision after healing.

The Malar Bones

Laterally the malar bones form the buttress and contour of the cheeks. The human has a marvelously rapid protective reflex that turns the head at the instant of impact. The brunt of many blows is borne by the malar bones. Their attachment points — frontal, temporal, and maxillary (infra-orbital and alveolar) — are weaker than the body of the bones (Figure 13). Only occasionally is the bone fragmented. Displacement, however, can be extreme because the large underlying maxillary sinus space provides no support. Rapid swelling tends to obscure the true extent of the cave-in. The line of fracture in the orbital floor tears the

Fig. 14 — Method of examining the infra-orbital rim for malar fracture with comparative thumb palpation from position behind the patient.

periorbita. Hematoma supports the globe at normal level for a week or two, but when it resorbs the globe drops. This global displacement and the shift of the bony attachment of the inferior oblique muscle can result in diplopia of very disabling character. The same hematoma dissects under the bulbar conjunctiva to the limbus. This subconjunctival hemorrhage should warn the examiner that here at least is one swollen and ecchymotic eye that should not be made the butt of doorknob jokes. The humor incident to a "black eye" loses much of its flavor when the patient returns in two weeks with a flattened face and diplopia.

A chin-nose position film as of the maxillary sinuses is quite diagnostic of malar fracture. The presence or absence of displacement should not be determined finally by the film, however. Its angle may not define significant malposition. The palpating thumb placed along the infra-orbital edge may reveal a step-down that is not well shown on the film (Figure 14).

Infra-orbital Rim

Since the weak point of fracture on the infra-orbital rim is at the infra-orbital foramen, hypesthesia of this sensory nerve is usual with malar fracture. Hence numbness of the upper lip and nasal ala on the side of

Fig. 15 — Techniques of malar fracture realignment. Reversal of the injury force is the basic objective.

Fig. 16 A and B — (A) Orbital floor implant with silicone rubber sponge for long-standing orbital floor depressions. (B) Intramaxillary antral support of recent orbital floor ("blow-out") fracture with indwelling silicone rubber palisade in three insertional layers.

the injury is an important diagnostic sign. So also is the presence of blood in the maxillary sinus due to tear of the mucoperiosteum. Sufficient depression of the malar arch can impinge on the mandibular coronoid, and mouth closure will then be difficult.

Reposition of the malar bone can be accomplished in several ways; there is no best way for all fractures. The objective of reversing the injury force to realign the fragments demands familiarity with a number of approaches (Figure 15). A lateral blow can be reversed through a temporal hairline and temporal fascia incision with the elevator placed beneath the malar arch. Inferior displacement of the body can sometimes be corrected by manipulation with a bone hook externally or elevation in the buccal sulcus intra-orally. Posterior impaction of a substantial fragment of the infra-orbital rim may require direct exposure through a well-placed infra-orbital incision and retrieving of the fragment with a short strong hook. This exposure allows direct wiring across the frac-

ture line. As with nasomaxillary fragmentation this is accomplished with a drill, fine drill points, and fine steel wire loops (Figure 12).

It is inadvisable to attempt manipulation of the malar bone with a towel clip. This endangers facial nerve filaments when the tenaculum slips. Entering the maxillary sinus through the canine fossa is necessary only in special instances. The maxillary opening requires sacrifice of bone in opening the sinus that would be advantageous for support of the repositioned malar.

If the comminuted shell of the orbital floor is lost into the maxillary antrum ("blow-out fracture") it is better to use incisional access to elevate the orbital contents and visualize the fragmentation directly. Canine fossa opening for digital manipulation and elevation of the fractured segments may be helpful. The inferior oblique muscle and attachment must be anatomically replaced. Three-segment palisade intra-antral support with fine, closed-mesh silicone rubber sponge left

Fig. 17 — Silicone rubber sheet substitution for loss of orbital floor fracture fragments in acute injury.

in place six to 10 weeks will eventuate in a good result (Figure 16-b). If support fragments are deficient the orbital floor can be supplemented with a properly placed silicone rubber sheet (Figure 17). When necessary the fragments of the infra-orbital rim are wired directly into position (Figure 12).

Frontomalar Fracture

Occasionally the frontomalar fracture line will not hold in anatomic reposition after reduction. Direct wiring to the frontal abutment through a lateral brow incision (Figure 11) with or without infra-orbital wiring (Figure 12) is then useful. On rare occasions it can be supplemented with binder traction from a screw inserted in the body of the bone to a head cap appliance. An impaling Kirschner wire carried across to firm supportive bone on the opposite side is sometimes a simple and useful fixation method.

Solid healing in malposition due to neglect of the acute malar fracture is best corrected by osteotomy refracture along the four main fracture lines and reclamation of the malar bone itself for replacement and direct fixation (Figure 12). The results are generally superior to those obtained with implantation of iliac bone or diced cartilage.

When the position of the main body of the malar-maxillary complex poses no problem, but long-standing orbital floor deficiency cripples ocular fusion and disables cosmetically, elevation and support can be helpful. This may be effected with autogenous or despeciated bone implant or silastic sponge implant. The latter is shaped and then divided into two segments by anterior-posterior division. One half is inserted through a medial two-third infra-orbital working incision and crowded with its taper laterally. Then the medial half is inserted and the cut edges matched along the division line (Figure 16-a).

Complex Fractures

The challenging injuries of the facial skeleton are those that combine injury to all or most of the component bones (Figure 18).

Multiple fractures of the facial skeletal components or total fracture are not uncommon. Extraordinary disruption is compatible

with life and occasionally occurs in the absence of intracranial or other injury.

Direct inspection, palpation, and x-ray study serve to orient one with the problem and define the repair sequence. The order of treatment is airway establishment, blood replacement, general assessment, adequate restorative pause, and then integration of the reparative procedures in one orderly operative sequence.

Skeletal repair techniques should not be inordinately complex; simplicity in reduction method and in fixation methods should be the rule. A certain amount of gadgetry is necessary. It can be grossly overdone; then the apparatus becomes more of a problem than the injury. A "Rube Goldberg" solution is a poor substitute for simple direct fracture exposure and wire loop or pin fixation. Incisional access (Figure 11) will expose the

Fig. 18 — Complex facial injuries may be unilateral as above or bilateral. The mandible may or may not be involved. The whole problem is divisible into individual component parts — each amenable to relatively simple solution.

usual fracture sites directly. Anatomic realignment with direct vision is more certain than is tactile realignment through an edematous, ecchymotic soft tissue mass. Permanent wire fixation is accomplished through the incisional exposure with fine loops passed through fine drill holes (Figure 12). In multiple fractures the most lateral or superior fragment is attached first to the unfractured skeleton. The other fragments are attached in succession — downward and medialward.

Soft Tissue Repair

When general circumstances make surgical delay advisable, facial soft tissue injury can be protected with a compression dressing for twenty-four hours. If longer delay is unavoidable the soft parts can sometimes be cleaned, trimmed and repaired at bedside with the aid of local anesthesia. Access to the skeletal fragments through the lacerations is frequently important for direct wiring and ideal fixation; on occasion it is necessary to open repaired lacerations for this purpose. The greatest aid to ideal soft tissue approximation is perfect skeletal realignment.

Debridement of facial wounds can be conservative but must be thorough as to depth. All surface tattooing should be removed. Suture materials of 6-0 and 5-0 gauge with comparable needles should not be exceeded. Gentle handling of tissues is mandatory. Magnifying loupes increase the precision of repair (Figures 19-a, 19-b and 19-c).

Closure must be in layers with no tension exerted at the skin surface. For repair

Figure 19 (b)

Figure 19 (a)

Figure 19 (c)

Fig. 19 (a), (b), (c) — The basic principles of soft tissue repair — careful debridement, closure in layers, fine instrumentation and suture, loupe magnification.

of lacerations into mucosal lined spaces, thorough mucosal approximation is the primary step. Skin sutures should not be placed wide of the laceration margins. Subcuticular techniques are excellent in soft tissue repair. The outer suture can remain for a week. Adhesive supports can be applied in addition to skin sutures. Edema and serum pooling are prevented by elastic dressings; circumferential are best when possible. Crusting at the repair lines is undesirable and is prevented by moistening the dressings at the incision lines with dilute neomycin solution for the first three days. Thereafter, soften-

ing ointment of neomycin — gramicidin — polymixin-type is desirable. Interrupted sutures must be divided in 48 hours and removed in 72 hours. Adhesive bridging is applied for support at the time of suture division. Antibiotics and good facial blood supply reduce infection to a minimum as long as debridement is adequate and mucosal surfaces have been properly approximated.

After the primary three weeks healing is complete, the facial scars should be massaged lightly with bland skin cream for five minutes four times a day to improve mobility and elasticity in the healing scar.

Mr. Barzun Comments Community Life in Medicine

We came alone into this world and expect to leave it the same way. When we are ill, we feel similarly alone in our misery; being sick is a highly individual affair, which makes us long for personal attention, not just "personalized" on the surface; and this is what our system overlooks, what too many doctors fail to understand.

Now no one but an ignorant savage is "down on doctors" or begrudges them their authority. . . . One understands that each good practitioner has probably more patients than he can handle. It is natural, efficient, normal to apply to them the methods of mass production. . . . Medical techniques have the impersonality of science — tests, charts, averages. All this is right and proper, but one must ask how far the doctor's training as a healer is damaged by it. The patient survives, but why should he spend his worst moments in an atmosphere wholly mechanical and metallic?

If he goes to the hospital, he finds it has become a factory run by engineers. . . . Say you have been in pain, unable to sleep. Finally you drop off. Ten minutes pass: you are brusquely waked up: the nurse is there to give you a sponge bath. It is routine. You are bright enough to see that if every patient chose his own time, the system would go to pieces. But the fact remains that you have been deprived of one of the rights of the sick. Hardly back from death's door, you have been forced to "co-operate" again. Your illness is not your own, it's a segment of community life.

Jacques Barzun: *When the Doctor Is a Pill* (in *God's Country and Mine*) 1954

Without my work in natural science I should never have known human beings as they really are. In no other activity can one come so close to direct perception and clear thought, or realize so fully the errors of the senses, the mistakes of the intellect, the weaknesses and greatnesses of human character. — Goethe

The tyrant dies and his rule is over; the martyr dies and his rule begins.

— Kierkegaard

He doesn't feel he "suffers" from hypertension

**Butiserpazide® lowers blood pressure
so smoothly that patients are often untroubled
by either disease or therapy**

By switching patients to BUTISERPAZIDE you may be able to free them of much of the burden of hypertension. Clinical comparisons have shown that many respond with (1) smooth, uniform lowering of blood pressure¹...at times to levels *below* those attained with previous therapy²; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness²; plus

(3) "...lowered incidence of drug side effects."²

And there's an added advantage: the usual dosage is just 1 tablet once or twice daily, often without need for supplementary therapy. (BUTISERPAZIDE provides not only hypotensive and diuretic action, but a mildly sedative effect as well.) Isn't this the way to take the suffering out of hypertension?

You have a choice of 2 strengths:

Butiserpazide®-25

Prestabs®* Tablets

in mild to moderate cases, often effective at half the usual thiazide or thiazide/reserpine dosage.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†; Hydrochlorothiazide 25 mg. (¾ gr.); Reserpine 0.1 mg.

Butiserpazide®-50

Prestabs®* Tablets

controls many moderate to severe cases without any need for ganglionic blockers, or other more potent agents; if such agents are needed, their dosage can be cut in half.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†; Hydrochlorothiazide 50 mg. (¾ gr.); Reserpine 0.1 mg.

*15 mg. of Butisol (butabarbital), plus the other ingredients, in outer layer; 15 mg. of Butisol (butabarbital) in a specially coated core for delayed action, to approximately equalize duration of action for all components.

Contraindicated in presence of renal impairment, peptic ulcer, ulcerative colitis, or mental depression, and in patients with porphyria or those sensitive to any component. **Warning:** Coated potassium tablets, sometimes administered in conjunction with anti-hypertensive therapy, may be associated with small bowel lesions which have led to obstruction hemorrhage, and perforation. Surgery has been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occur. **Precautions:** Exercise caution in hepatic disease, diabetes, surgery, coronary artery disease, epilepsy, E.S.T., and in patients receiving digitalis. **Side Effects:** Electrolyte imbalance, hyponatremia, hypochloremic alkalosis and/or hypokalemia, hyper-

uricemia and gout, bradycardia, drowsiness, skin rashes, hangover, systemic disturbances, weakness, leg cramps, diarrhea, epistaxis, dizziness, urticaria, dry itching skin, nausea, vomiting, palpitation, superficial skin bruises, headache, dehydration, paresthesias, photosensitivity, pancreatitis, jaundice, xanthopsia, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, nasal congestion, hypotension, lassitude, loose stools, anorexia, bizarre dreams, peptic ulcer, ulcerative colitis, mental depression. (Ammonium chloride, which may be administered to reverse hypochloremic alkalosis, should not be given to patients with hepatic disease.) **Before prescribing or administering, see package insert.** †Warning: May be habit forming. **Usual Adult Dosage:** Butiserpazide®-25 or Butiserpazide®-50: 1 tablet daily or b.i.d. **References:** 1. Johnson, H. J., Jr.: Penna. M. J.: 67:35, 1964. 2. Coodley, E. L.: Curr. Ther. Res. 4:460, 1962.

McNEIL

McNEIL LABORATORIES, INC.,
FORT WASHINGTON, PA.

She simply sits while the party goes on around her, already used to being the girl who is left out. She tries to lose weight—but her emotions won't let her. She becomes irritable and depressed when she doesn't eat, and anxious when she considers her future. So each time she gives up.

"What can I do?" she asks when she visits your office. "How can I ever stay on a diet and lose weight?"

A PARTICULAR COMBINATION OF ACTIONS

Ambar[®] #2 Extentabs[®]

methamphetamine hydrochloride 15 mg., phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

FOR THE NEEDS OF THE DIETING WOMAN

A. H. Robins Co., Inc.
Richmond, Va. 23220

A-H-ROBINS

Ambar is formulated to specifically meet both the physical and emotional needs of the woman who is trying to lose weight. *Methamphetamine hydrochloride* has a powerful suppressant effect on the appetite and also provides a gentle psychic lift to improve mood and encourage activity. The *phenobarbital* component, through its classic calming action, helps control irritability and anxiety, and helps counteract excessive CNS stimulation.

Also available: Ambar #1 Extentabs[®]—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY / Indications: Ambar suppresses appetite and helps offset emotional reactions to dieting. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. See package insert for further details.

Management of Alveolar Fractures

ALBERT HOHMANN, M.D., D.D.S.*
St. Paul, Minnesota

INJURIES TO THE inferior and superior maxilla are seen more frequently now in association with the increasing number of traffic accidents. There is a higher incidence of limited injuries to the jaws because more motorists are wearing seat belts. Often they suffer alveolar ridge or nasal fractures. This increase of limited trauma to the facial bones should alert the family physician to the fact that he, rather than the specialist in the large emergency centers, will often be called to render initial treatment and advice. Frequently, cases which at first glance appear as simple problems turn out to be complicated.

Physicians attending accident victims are well trained in establishing an adequate airway and caring for soft tissue and bone injuries. The dental aspects, however, may escape attention and therefore be neglected.

Hazards of Alveolus Fracture

1. Fractures of the alveolus of the inferior and superior maxilla are the most common jaw injuries in children and young adults.
2. One or several teeth may be damaged or displaced.
3. In children under twelve years of age, both the first and second dentition can be injured.
4. Teeth, especially those of the second dentition, represent one of the most precious units of the human body and must be preserved if possible.

Diagnosis of Alveolar Fractures

Inspection and Palpation of the Alveolar Ridge

Extra and intra-oral examination is tedious and sometimes painful. Because of the pain, swelling and trismus, especially if

*Clinical Associate Professor of Otolaryngology, University of Minnesota and a member of Otolaryngology Professional Associates, St. Paul, Minnesota.

fractures are present, local or general anesthesia may be necessary for an adequate examination. An abnormally mobile alveolar segment indicates fracture. Most commonly the alveolar segment may be: (a) totally avulsed, (b) pedicled on one mucoperiosteal flap, or (c) suffering only vertical or horizontal linear fracture.

Determination of Dental Injury

Dental injuries can involve: the enamel, the dentin, and the pulp of one or several teeth. The degree of damage to these three structures can range from a hair-line crack in the enamel and dentin of the crown to complete fractures involving the crown, the root, or both. The use of a bright headlight, together with head and laryngeal mirror, for transillumination of the teeth is very helpful.

Assessment of the Degree of Malocclusion

In order to detect any malocclusion it is always mandatory to ask the patient if his teeth mesh normally and feel normal. Often the only clinical evidence of the alveolar fracture is a loose tooth which "blocks" the occlusion. All teeth must be tested for first, second or third degree loosening. This is best done by forcefully manipulating each tooth between the thumb and index finger in the horizontal and vertical direction.

X-ray Examination

The physician should always specifically request "occlusal views of the mandible and maxilla" and intra-oral dental x-rays. Occlusal views give much more detailed information about the contour of the upper and lower alveolus and the position of the fractured teeth in relationship to the dental arch than do routine roentgenograms of the facial bones.

Examination of Nasal Cavity, Buccal Alveolar Sulcus, Lips and Floor of the Mouth and Tongue

Occasionally an empty socket, especially in the upper jaw, may indicate a more serious injury than one would suspect from a cursory examination of the maxillofacial region. If no root or crown fragments remain

in the socket or oral cavity or have not been found at the site of the accident, one should be suspicious that the missing teeth or their fragments may have been driven into the adjacent structures. The upper lip, the nasal cavity or the alveolar buccal sulcus may harbor the missing parts. Since they are all radiopaque, they can be traced by x-ray examination and should be removed before infection develops.

Treatment of Alveolar and Dental Injuries

The treatment of alveolar injuries is primarily aimed toward restoring the patient's exact pre-accident occlusion. It should be remembered that occasionally the pre-accident occlusion was not normal or ideal. For a large number of patients an "over- or cross-bite" represents normal occlusion. Secondly, attention should be directed toward preservation of the fractured teeth. This is especially important when the canine central incisors and first molars are involved, since these teeth are the most difficult ones to replace by prosthetic means. The last consideration should be given to the repair of the injury by prosthetic means.

Emergency Care

An adequate airway and the control of bleeding should be provided immediately. In the past the primary intention of protecting and securing an adequate airway often leads to a much too vigorous attack on loose teeth and alveolar bone fragments which were usually discarded or sent to the pathology laboratory as surgical specimens. This is no longer necessary nor in the best interest of the patient. If the injured tooth or root has reasonable support from the socket, great care should be used to preserve it. In the acute care, badly damaged teeth and bone may be saved by gentle manipulation and protective ligature anchorage to intact teeth. Only fractured crowns which are loosely attached to the gingiva and therefore represent a hazard of inspiration should be removed immediately, while fractured roots adequately embedded in the bony tissue must be preserved for possible future prosthetic foundations. In fact, all intact teeth and al-

veolar bone fragments which are so loose that they might represent aspiration problems should be removed in the emergency room and preserved in saline solution, to be reimplanted when definitive treatment is carried out.

Definitive Care

The closed or open reduction of the alveolar bone is usually combined with fixation of the teeth by means of wire loops and metallic or acrylic splints.

The fixation of a large alveolar segment hinged on the mucoperiosteum or one cortical layer can usually be done by closed approach with loop-wire support to solid neighbors or to a dentally fixed wire arch.

If the classical loop wire fixation is too traumatic or not possible, it can be avoided by protective splinting with quick setting acrylic or surgical cement.

Open reduction may occasionally be required when a large segment has been totally avulsed. This is done by placing stainless steel wire loops through the loose and solid segments.

Complications and Conclusions

Loss of the alveolar buccal sulcus can be

most disabling and can even make later denture preparation impossible without sulcus inlay skin graft. Therefore mucosal avulsions from the buccal alveolar sulcus require careful replacement and suturing. Stent support for several days may be helpful in maintaining the position of a flap. Teeth which suffer injury — be it only a concussive blow — should be assessed periodically for several years. Delayed pulp deterioration is not uncommon and should be diagnosed before tooth discoloration, infection or apical cystic resorption occur so that root canal filling can be done. The simplest diagnostic follow-up is the test for sensitivity with a spicule of ice. The patient can be instructed in this, or he can be periodically re-evaluated by his dentist.

Fracture of the alveolar segment of the mandible and maxilla is an important injury principally because of the teeth involved. Adequate and prompt treatment will restore the normal function of the teeth and a cosmetically and esthetically pleasing appearance. Mis-diagnosis and incorrect treatment, however, can result in irreparable loss of the alveolar bone and teeth together with severe occlusion and articulation problems.

Why Doesn't the Doctor Tell?

It is somewhat strange, that a class of men who can command such interesting, extensive, and instructive materials, as the experience of most members of the medical profession teems with, should have hitherto made so few contributions to the stock of polite and popular literature. The Bar, the Church, the Army, the Navy, and the Stage, have all of them spread the volumes of their secret history before the prying gaze of the public; while that of the Medical Profession has remained hitherto, with scarcely an exception, a sealed book. And yet there are no members of society whose pursuits lead them to listen more frequently to what has been exquisitely termed, The still, sad music of humanity.

— Samuel Warren (1807-1877)

special formula for a special problem

*specifically formulated
for symptomatic
relief of sinus headache*

Sinus headache is not a single entity,
but a chain reaction of pain.
It is facial pain—deep, dull, aching and
nonpulsating. It is referred pain—
originating in the nose and sinuses but
felt at another site. It may become
generalized pain and tension in head and
neck. It is one or all of these.

The Sinutab formula is designed
for symptomatic relief of sinus headache.

It provides two analgesics to relieve
pain and discomfort...an effective oral
decongestant to reduce mucosal congestion...
and an antihistamine to help
control allergic manifestations.

Side Effects: Epigastric distress, drowsi-
ness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive
or operate machinery if drowsiness occurs.

Use with caution in patients with thyroid
disease, heart disease, hypertension, diabetes
or kidney disease. Excessive dosage or
prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

WARNER-CHILCOTT
Morris Plains, N.J.

SINUTAB[®] for sinus headache

Each tablet contains
150 mg. acetaminophen,
150 mg. phenacetin,
25 mg. phenylpropanolamine HCl,
and 22 mg. phenyltoloxamine
citrate.

FIGHTING CANCER WITH FILMS...

...is not news. What's news is that we've embarked on the most ambitious film program *for professional medical audiences* ever launched against a single disease. A half-million dollar film project is underway—with technical advice from the nation's leading medical authorities.

Five of these films are available now—

CANCER IN CHILDREN, DIAGNOSIS AND MANAGEMENT OF CANCER OF THE COLON AND RECTUM, ORAL CANCER, NURSING MANAGEMENT OF THE PATIENT WITH CANCER, and THE DENTIST AND CANCER. The balance will be released in 1967-1968.

As pioneers in the usage of medical films, we know their value as teaching tools. Our Units across the country know, too. Films are a vital part of their professional educational programs. We hope you will contact *your* local ACS Unit about this outstanding new series.

AMERICAN CANCER SOCIETY 

Fractures of the Mandible

G. S. FITZ-HUGH, M.D.*
Charlottesville, Virginia

IN A WORKING classification of facial bony injuries, the less frequent ones involving the frontal sinuses are considered in the upper facial group; the midfacial, the more common, including those of the facial bones such as nasal, internal orbital floor, maxillozygomatic complex, maxillae, zygomatic arch, etc. are categorized as midfacial fractures, and those of the mandible, occurring almost as often as the midfacial group, as lower facial fractures.

The otolaryngologist in the management of midfacial injuries will often encounter fractures of the mandible as part of the multiple injury complex presented by the patient, usually as the result of an automobile accident. Or in the event no fracture of the mandible exists, he may find it advantageous to utilize this bone as a substantial, stable, fixed point which will be useful in the reduction and immobilization of severe midfacial fractures such as the Le Fort I, II, and III, and in the unilateral maxillozygomatic types.

Diagnosis

Fractures of the mandible are not difficult to diagnose, especially if one is aware of the fact that significant bony injuries may occur with minimal evidence exhibited in the overlying soft tissues. Supporting evidence of fracture includes: decreased and abnormal mobility of the lower jaw, localized areas of swelling, crepitation, salivation, etc. All fractures or suspected fractures of the mandible should obviously have radiographic examinations. Fracture of the symphysis, horizontal ramus and angle may be readily detected. Fractures of the condylar processes may be difficult to demonstrate and will require special techniques. It should be recalled that in the case of fractures of the lower jaw, the muscles of mastication will influence the

*Chairman, Department of Otolaryngology, School of Medicine, Otolaryngologist-in-Chief, University of Virginia Hospital, Charlottesville, Virginia.

position of the fragments. In contrast, there is no such action upon the fractures of the other facial bones. Fractures of the mandible are usually multiple, and those of the condylar area may be overlooked. Fracture displacements with dislocation of the condylar head from within the glenoid fossa are not as difficult a problem as one would anticipate. The occlusion of the first molar teeth in the upper and lower jaws may be used as the key for proper reduction of the fracture. It must be remembered, though, that in certain cases pre-traumatic malocclusion may have existed, and this should be considered physiologic and functional.

Treatment

Antibiotics

Antibacterial drug usage is indicated in fractures involving the tooth-bearing areas, as they will invariably be compounded intra-orally, thus creating an entrance for infection.

Fig. 1 — Winter dental arch splint mandibulomaxillary fixation. Craniomandibular and craniomaxillary suspension. Transosseous wiring.

X-Rays

In general, time should not be wasted in the emergency room struggling for definitive radiologic views of the facial bones in a case with multiple body injuries. Such films are better ordered later when more accurate ones can be had. In the case of a severe mandibular fracture displacement temporary support by wiring or a sling dressing may be useful in minimizing bleeding, edema and discomfort.

Closed Reduction

The vast majority of fractures of the mandible containing an adequate number of teeth may be managed by reduction and then immobilization, by placing the teeth of the lower jaw in centric occlusion against those of the upper jaw. First a prefabricated malleable metal arch splint of the Winter, Erich, or Jalenco types is fixed to the teeth of the upper dental arch with stainless steel wires (24 gauge). Next, after the mandibular fractured fragments are properly positioned, a similar splint is applied to the lower teeth. Then a separate segment of splint is applied to the teeth of each fracture segment. The procedure may be performed under general or local anesthesia. The splints contain hooks

Fig. 2 — Erich dental arch splint mandibulomaxillary immobilization for subcondylar fracture.

or lugs, and to these (after complete recovery from general anesthesia when used) elastic bands are placed between the upper and lower lugs in strategic positions in order to bring the teeth into proper position, thus reducing and immobilizing the fracture (Figure 1). Mandibulomaxillary or intermaxillary fixation is continued for a period of four to six weeks. This method of treatment was formerly considered a temporary one to be utilized only until more elaborate intra-oral appliances and prostheses could be prepared. Its success, however, has led to its use in the majority of cases as a permanent solution.

Open Reduction

In fractures of the edentulous mandible and in special situations where teeth are present, open reduction by the extra-oral or intra-oral approach is our first choice. This method is particularly applicable to fractures in uncooperative, mental, and alcoholic patients. Under general or local anesthesia, the fractured bone is exposed by the external or intra-oral approach (usually the

former). The fragments are perforated with a bone drill, care being taken to remain above or below the mandibular canal in order to protect its contents. The fragments are wired directly (trans-osseous) in proper position with stainless steel after reduction of the fracture. Mandibulomaxillary fixation is sometimes utilized as a supplement to the trans-osseous wire fixation.

Circumferential wiring of the mandible, using as a splint the patient's denture or a Gunning type of appliance, is effective in the immobilization of a fractured edentulous mandible in certain cases. Intramedullary wire fixation with a Kirschner pin may be utilized alone or as a supplement to other means in the management of a fractured mandible without teeth.

Immobilization of the Edentulous Fracture

Plastic headcaps for immobilization or suspension purposes are utilized very infrequently now, usually only in fracture of the edentulous mandible with bilateral subcondylar fractures. Under the best conditions, this treatment modality is uncomfortable and usually unsatisfactory. Extra-oral skeletal pins are now employed even more infrequently than the headcaps.

Condylar Fractures

Fractures involving the condyles of the mandible are interesting because they do so well with minimal treatment. They may be intracapsular or extracapsular (subcondylar). As the neck of the mandible is its weakest point and the glenoid fossa is quite solid, condylar fractures are common. If the condyle is displaced, bony contact is usually maintained within the capsule and periosteum. Healing in the malaligned position will result in no appreciable joint dysfunction. If actual dislocation from within the fossa occurs, fibrous pseudoarthrosis develops, and this is an acceptable sequela. Immobilization of the joint for a period of ten to fourteen days usually suffices to prevent a future painful joint or a "bite of convenience" (Dingman). Immobilization is accomplished by any one of the methods that have been previously mentioned (Figure 2).

Fig. 3 — Mandibulomaxillary immobilization which may be combined with transosseous wire fixation. Useful in children. Wires may be sheathed in polyethylene tubing.

Comment

What to do with the teeth damaged or undamaged in or adjacent to the fracture is a problem requiring individual consideration. Good teeth and those that may be useful for stabilization purposes should be retained if at all possible. Fractured teeth may be salvaged and restored to usefulness at a later date. Those teeth in the fracture line of a moderate to severely injured mandible are often extracted by the dental consultant.

Children

Fractures in children are rare compared to those in adults. This is mainly due to the lack of rigidity in the young and to the elasticity of the bone. When fractures do occur, however, they often present special problems. Deciduous teeth are unsatisfactory for the application of metal arch splints and mandibulomaxillary fixation. Open reduction with interosseous wiring becomes necessary. If immobilization of the entire mandible is necessary in the event of fractures involving the condyles, this may be accomplished by wires and elastic bands between the pyramidal aperture of the maxillae and mandible

(subcutaneous and intra-oral) as demonstrated (Figure 3).

Length of Fixation

The time factor in immobilization of mandibular fractures varies, depending upon the severity of the injury, the presence of teeth, and the age of the patient. Generally speaking, the maximum period of fixation should be six weeks and the minimum three weeks.

Acute dislocations of the temporomandibular joint are often spontaneous and not associated with trauma. The condyles are displaced anteriorly out of the glenoid fossae. If reduction is delayed an hour or so after sedatives have been administered, reversing the malposition by manual manipulation will readily reduce the dislocation.

Summary

Otolaryngologists have a primary interest in the management of upper and midfacial injuries. As fractures of the lower face (mandible) will often be a part of the injury complex, it is reasonable and necessary that they should be knowledgeable with regard to the management of such. In a general manner some of the problems associated with them are included in this brief presentation.

Babylonian Remedy for Gastric Complaint

If a man has stomach pain, let the man kneel on his feet and have burning juice of cassia poured over him, and he will recover. If *ditto*, let him kneel on his feet and let cold water flow over him. If *ditto*, place his head downwards and his feet up, strike his cheek forcibly, rub him violently, say to his stomach, "Be Good."*

Bell's Palsy and Post- Fracture Facial Paralysis

GEORGE E. SHAMBAUGH, JR., M.D.*
Chicago, Illinois

THE FACIAL NERVE is unique, having the longest course through a rigid bony canal of any nerve in the body. As a result this nerve is paralyzed more often than any other motor nerve in the human body. Ninety percent of cases of facial paralysis originate from disease occurring in the intratemporal course of this nerve (Cawthorne), only a small percent being of intracranial origin and about 5% due to a lesion distal to the stylomastoid foramen. Being nearly always the result of a lesion in its course through the temporal bone, a case of facial paralysis should first of all be considered an otological problem and should be referred to the otolaryngologist for diagnostic and prognostic studies. The reasons for such a referral will become evident as we consider the etiology and treatment of peripheral facial nerve paralyses.

Bell's Palsy

One hundred and fifty-six years ago, Charles Bell, anatomist and surgeon, read before the Royal Society of London an essay on the Nerves of the Face. That same year he was knighted for his neurophysiologic discoveries which included this essay in which he demonstrated the sensory innervation of the skin of the face by the *fifth* nerve, and the motor innervation of the muscles of expression by the *seventh* nerve. He proved his points by three cases of facial palsy following division of the seventh nerve at or near the stylomastoid foramen, one by a pistol ball, one by the horn of an ox, and the third due to extirpation of a parotid tumor: . . . "and the immediate effect has been the horrible distortion of the face by the prevalence of the muscles of the opposite side . . . and that distortion is unhappily increased when a pleasureable emotion should be reflected in the countenance." This vivid

*Professor of Otolaryngology, Northwestern University; Chief Editor, Archives of Otolaryngology.

and picturesque description by Bell of seventh nerve paralysis has never been surpassed.

At first all cases of peripheral flaccid facial nerve paralysis were termed Bell's palsy, but as specific lesions occurring along its course were shown to involve the nerve by pressure, infiltration or trauma, the term Bell's palsy came to be applied only to those cases where no such external lesion could be demonstrated, and where the paralysis came on abruptly in an otherwise healthy individual.

Peripheral Facial Nerve Paralysis

Surgical Trauma

Among the specific lesions that can cause a flaccid peripheral facial weakness or complete paralysis, the most frequent is surgical trauma during an ear operation, with skull fracture involving the temporal bone gaining in frequency as the power and speed of automobiles continue to increase. Mastoid disease, especially cholesteatoma and carcinoma of the ear, are not rare causes for facial paralysis. Less common causes are glomus jugulare tumors, neurinoma of the facial nerve, acoustic neurinoma, and meningioma involving the temporal bone, all of them considered benign tumors, although glomus tumors and meningiomas are locally invasive and difficult to eradicate surgically. Facial paralysis is an early symptom of carcinoma of the outer or middle ear.

Idiopathic Facial Paralysis

The most frequent cause for peripheral flaccid facial paralysis is the idiopathic variety known today as Bell's palsy. The etiology and pathology are only partially understood. In 70% of cases a history of abnormal cooling of the mastoid region may be elicited, while 30% follow an emotional shock or abnormal stress. When the nerve is uncovered surgically within the first few months after onset a marked edema of it is observed, involving nearly always the vertical mastoid portion. Clearly, the paralysis has been the result of compression of the nerve in its rigid bony canal by this edema,

just as pressure upon any nerve blocks the transmission of nerve impulses, such as the familiar temporary loss of sensation in the hand when slept upon in a cramped position.

Bell's palsy recovers spontaneously and completely in the majority of cases, but in 15% to 25% of cases recovery is imperfect and incomplete, with spasm and synkinesis* combined with residual facial weakness, permanently marring the beauty of the features especially "when a pleasureable emotion should be reflected in the countenance." It is with this group of cases that the otologist should be concerned, since he can help to minimize the eventual deformity by timely release of pressure upon the nerve.

Pathologic Events in Bell's Palsy

The pathologic course of events in Bell's palsy is believed to be the following: local chilling or emotional shock causes an initial vasoconstriction, followed by venous congestion and edema. These same events in any other nerve will go unnoticed, but the facial nerve in the rigid confines of the fallopian canal becomes compressed by the edema, with blocking of electrical conductivity and nerve impulses.

The Effect of Pressure

The pressure, sufficient to block all nerve impulses, causes a damming up of axoplasm which continues to flow out from the parent cell body in the brain stem. As long as some axoplasm can squeeze by the compressed region the axon does not die, though it cannot transmit nerve impulses. If the pressure is sufficiently great the peripheral axon, entirely cut off from replenishment of axoplasm, will use up its axoplasm by catabolism, and will die. The result is then exactly the same as though the nerve had been sectioned. For a few days the distal end of the axon has continued electrical excitability as it continues to receive oxygen through the Schwann cells. Then its axoplasm begins to be used up by catabolism and begins to fragment with a gradual decline in electrical excitability. The myelin coating around the axon then fragments; but the Schwann cells, which are inde-

*See Test Your Word Score Page 1028.

pendent of the cell body of the neuron, remain, increase in size and number, and become phagocytic. They next proceed to engulf the axonal and myelin debris, and finally fill the connective tissue tubule of the nerve fiber. Meanwhile, the parent cell body and its nucleus, deprived of nutrients normally brought back to the cell through the axon, sickens, as shown by loss of Nissl substance and a swelling of the cytoplasm. Soon, however, a growth cone develops at the proximal end of the sectioned axon and begins a very active proliferation of protoplasmic processes and pinocytosis with taking in of nutrients that travel back in the axon to the cell body, which in turn becomes healthy again.

The Growth Cone

The growth cone of a young or regenerating axon can be studied in the living state by phase-contrast time-lapse cinematography. The sending out of protoplasmic processes seeking a favorable pathway for growth of the new axon results in branching, so that one regenerating axon often enters several neural tubules leading to widely separated muscle bundles. This accounts for the synkinesis always seen following regeneration of a severed or degenerated facial nerve. Some of the neural tubules will fill in with fibrous tissue closing them or reducing them in size before they are entered by a regenerating axon. The result will be failure of muscle fibers to be reinnervated, while other muscle fibers will be innervated by a very thin axon that remains unmyelinated and therefore uninsulated. This accounts for the muscle spasm and mass movement that follows regeneration of a facial nerve.

Surgical Decompression

The problem in each case of Bell's palsy is to determine when the pressure on the nerve is sufficient to begin causing axonal death and then to surgically decompress this early enough to relieve the pressure before many axons have died.

Optimum Time for Operation

Fortunately, the electrical excitability

test can indicate this. As long as the nerve on the paralyzed side shows normal excitability it is safe to temporize, but daily retest is indicated. As soon as this test shows progressive reduction in electrical excitability there is evidence that the pressure is sufficiently severe and prolonged to be causing axonal death, and prompt surgical decompression should be done. To wait an arbitrary two or three months and then decompress any case of complete Bell's palsy that fails to show beginning return of function is to wait until many or most of the axons are dead. On the other hand, surgical intervention *as soon as electrical excitability begins to decline* will be early enough to relieve pressure on the majority of axons while still alive so that they will recover without the permanent disfigurement of synkinesis, spasm, and incomplete reinnervation.

Exploration and Procedure after Fracture

Facial paralysis after skull fracture is due to edema, hemorrhage and often tearing or complete section of the nerve at the site of fracture. Just as Bell's palsy tends to recover spontaneously, so will many cases of facial paralysis recover after skull fracture, at least in part, without anything being done. However, the degree of and the chances for recovery are greatly improved by surgical exploration, decompression, and approximation of torn fragments in every case of facial paralysis that occurs immediately after a skull fracture. If the paralysis does not begin until a week or ten days after the fracture it is clearly due to edema and should be treated exactly like a Bell's palsy, with decompression only if and when electrical excitability begins to decline.

The facial trauma with marked edema of the structures that often accompanies skull fracture adds a diagnostic problem as to when the facial paralysis actually began. Not infrequently the facial paralysis is discovered only when the severe facial edema subsides. However, the more serious problems of cerebral concussion take precedence over facial nerve decompression, so that one may await the electrical excitability test results before deciding upon surgical ex-

ploration.

Summary

Bell's palsy and facial paralysis after skull fracture are otological problems:

First, because the site of lesion is within the temporal bone.

Second, because the decision as to whether or not to operate must be made by the otologist.

Third, because "all that palsies is not Bell's,"* and a careful otological examination is required to rule out other conditions that might be responsible for the paralysis.

Fourth, because surgical exploration of the fallopian canal and repair or decompression of the nerve requires the experienced otologic microsurgeon.

Finally, because the best chance of maximum recovery from Bell's palsy and facial paralysis after skull fracture requires timely surgical exploration and decompression or repair of selected cases.

*Cawthorne, Sir Terence.

First Use of Ether Anesthesia

In the National Statuary Hall in Washington, D. C., Dr. Crawford W. Long's statue bears the inscription: "Discoverer of the use of sulphuric ether as an anesthetic in surgery, on March 30, 1842, at Jefferson, Jackson County, Georgia."

Long had come to Jefferson to set up his practice in 1841, shortly after his graduation from medical school in Philadelphia. Soon thereafter, a "laughing gas" showman intrigued the townspeople of Jefferson with a lecture on the strange effects of nitrous oxide. Anxious to try the gas for themselves, several people asked Dr. Long for a sample. As it happened, the young doctor did not have any on hand but did have some ether, which, he assured them, would have about the same effect.

Some young men tried the ether in Long's office, became exhilarated, staggered about, laughed and behaved more or less as expected under the circumstances. But Long, more observant than most, noticed that as they staggered and stumbled about, bumping into furniture and bruising themselves, they seemed to feel no pain. Nor did he, himself, have any recollection of pain after joining the ether party and later finding bruises on his body. This set him to wondering about the possibilities of ether. If a small amount of it could mask pain of a bruise, would a larger amount be able to prevent the more extreme pain of surgery?

Dr. Long answered this question on March 30, 1842. James M. Venable, a participant in the ether experiments, had some tumors on his neck which he had delayed having removed because of his fear of pain. Long suggested that the use of ether might permit a painless operation. Venable agreed to its use. That night Dr. Long poured some ether on a towel and held it over the patient's nostrils until he fell asleep. When Venable awoke, he was astounded to learn that one of his tumors was gone. He had felt absolutely no pain during its removal. The first operation under ether anesthesia was a success and the fee, incidentally, was two dollars.

The doctor sees all the weakness of mankind, the lawyer all the wickedness, the theologian all the stupidity. — Schopenhauer

The Anatomy of the Lymphatics

Relationship
to
the
Dissemination
of
Malignancies
and
Infections

JOEL J. PRESSMAN, M.D.*
MILDRED V. BURTZ, R.N.*
Los Angeles, California

OUR CONCEPT of the role of the lymphatics in the dissemination of cancer of the head and neck, as well as in the spread of infection, is undergoing rapid revision. This is due primarily to the observation that materials within the lymph nodes pass directly into the vascular system, in addition to escaping through the efferent lymphatic channels which previously had been considered the only outlet. As a matter of fact, the vascular route may be the far more important of the two, since lymph flow is sporadic and meagre, whereas blood flow is constant and rapid. The quantitative differences, however, have not been established for one route as over against the other. This newer concept not only seriously affects our interpretation of the physiology of the entire lymphatic system and negates many of the old established theories concerning it, but contributes greatly to our knowledge of the route of dissemination of cancer cells and bacteria.

Once looked upon as a trap or reservoir, which limited the spread of migrant cells and bacteria, the lymphatics can no longer be looked upon as fulfilling this role. As a matter of fact, the exact reverse may be the case; by serving as a breeding ground and periodically discharging their contents directly into the bloodstream, they may act as supplemental sources of infection or as sites for the spread of carcinoma. *Lancet*, commenting upon these observations, stated that these newer hypotheses seriously challenged Virchow's concept of an effective lymph node barrier as expounded in 1860 and held to be factual ever since.

Review of Literature

An old adage** says that upon discovering something new, one has only to look in the old German literature to find that it had

*Division of Head and Neck Surgery, Department of Surgery, UCLA School of Medicine, Los Angeles, California.

**See Test Your Word Score Page 1028.

been discovered before. There has never been a better example than the subject under discussion. This supposedly new observation of a direct passageway directly from the lymph node to the vascular system, as it applies to both fluids and cells, was actually described in 1899 by Sigmond Von Schumaker in a paper entitled "Leukocytosis and the Efferent Paths of the Leukocytes in the Lymph Glands." Von Schumaker writes: "The smallest veins of the lymphatic substance present a peculiarity not only concerning their endothelial lining but also of another kind. It has been observed with extraordinary frequency that the vascular wall is penetrated by leukocytes . . . wholesale migration of leukocytes into the vessel walls rendered the latter to appear shredded in places and . . . passage of leukocytes from the lymph glands into blood vessels was observed. It seems likely, therefore, that direct migration of cells from the glands into the bloodstream took place." He then states that "the newly formed leukocytes in the lymph glands pass on their way to the bloodstream not by the longer route, via the thoracic duct, but by the much shorter one directly through the vessel wall," and suggests that "possibly the majority of leukocytes pass into the bloodstream from the lymph glands via the latter route." He then quotes Ribbert, who in 1890 wrote that "cells may pass from the lymph glands via the lymphatics into the blood or directly into the bloodstream. For more than 70 years, these observations remained relatively unknown, until it was our good fortune to rediscover them and once again bring them to light."

Migrating Tumor Cells

There are now numerous reports upon the presence of migrating tumor cells in the vascular system. It is likely these cells have passed from a primary site into the lymph node and directly from there into the bloodstream, most of them eventually being destroyed without establishing metastases. Parenthetically, this further suggests that a defense mechanism exists enabling the body to destroy cancer cells circulating into the bloodstream.

Our conclusions, as cited, resulted from experiments in which it was noted that air injected into a lymph node in conjunction with fluid passed directly and immediately into the bloodstream of the neighboring blood vessels and was seen simultaneously with the injection as bubbles in the bloodstream. We subsequently proved that this direct migration from the node to the vascular tree takes place in the instance of fluids as well and with cells the size of large bacteria; with the animals' own red blood cells and with Hela cancer cells. Having the advantage of modern advances in technology, our research techniques were more sophisticated than Von Schumaker's, particularly in the use of radioactive cells as tracers, but I am not certain that any evidence we have produced is more convincing than that Von Schumaker reported upon so many years ago. Many questions have been answered, as for example why the number and capacity of afferent channels to a node exceed those of the efferent channels and why lymphocytes do not disappear from the blood when all known lymphatic pathways are occluded by tying.

Practical Application

At the moment these observations seem to have little practical application to the everyday practice of medicine, except for the significance of one incidental observation which came about during the process of conducting these experiments. We believe it to be of the greatest practical importance. As has long been known, a lymph node discharges periodically into the efferent channel, and this discharge is increased by movements of the neck which increase pressures upon the node. The degree of pressure involved need not be greater than the physiological limits concerned with ordinary movements of the head and the contraction of the muscles of the region. Little has been written concerning the effect of pressure upon the emptying of an infected lymph node or one bearing malignant cells, and certainly little attention has been paid to this from the practical standpoint of everyday practice. This observation, however,

raises the question of the advisability of permitting large groups of students, for example, to palpate involved lymph nodes, thereby increasing intranodal pressure and possibly forcing the contents of the node into the vascular and lymph stream in large numbers. We have been equally concerned with the handling of lymph nodes in the course of surgical procedures. Definitive experiments carried out with this in mind have proven conclusively that during the course of surgical procedures upon the neck, a lymph node can be virtually emptied of its contents by pressure exerted upon it during the course of ordinary manipulations, this emptying taking place by escape through the efferent lymph channel, and the adjacent blood vessels as well. Using dyes, it was noted that the efferent channel distends notably as the result of minimal pressures upon the lymph node exerted by a palpating finger, and that cells not previously found in the bloodstream can be recovered from it during the course of such palpation and in greatly increased numbers in the efferent channel.

We have further observed that occlusion of the efferent channel can cause an escape of the contents of the lymph node. This raises the question of whether or not these untoward effects might not result from x-ray

therapy, biopsies, or excision of lymph nodes which destroy the escape routes, making the surgeon an innocent contributor to the dissemination of cancer beyond the node into the adjacent neighboring structures where, away from circulating fluids, they do not enjoy an equally good chance to encounter whatever protective measures the body provides and which are not as yet understood.

Our researches qualify as good research by reason of the fact that they ask more questions than they have answered. A larger number of workers now devoted to the study of the lymphatics will beyond all doubt provide some of the answers to the basic theoretical questions involved and, in so doing, provide answers to many questions of practical importance to all physicians concerned with the treatment of malignancies and infections, and for all those concerned with the lymphatic system in general.

Our present studies are concerned with electron-microscopic determinations of the micro-anatomy involved, since it is apparent that this interchange takes place as a result of the minute microscopic anatomy of the lymph node at the level of endothelial capillaries common to the lymphatic and blood vascular channels.

Remedies Derived from the Elm

The leaves, bark, and branches of the elm have the property of filling up wounds and knitting the flesh together: the inner membrane too, of the bark, and the leaves, steeped in vinegar, are applied topically for leprosy. The bark, in doses of one denarius, taken in one hemina of cold water, acts as a purgative upon the bowels, and is particularly useful for carrying off pituitous and aqueous humours. Many persons are of opinion that the bark of this tree, chewed, is a very useful application for wounds, and that the leaves, bruised and moistened with water, are good for gout. The moisture too that exudes from the pith of the tree, on an incision being made, applied to the head, causes the hair to grow and prevents it from falling off.

The Management of Metastatic Cancer

In
the
Region
of
the
Head
and
Neck

JOHN CONLEY, M.D.*
New York, New York

THE MANAGEMENT OF metastatic cancer in the region of the head and neck has evolved through the early and disastrous attempts at surgical control in the latter part of the nineteenth century, through three hopeful decades of the application of irradiation in the early part of the twentieth century, to the present status of a radical neck dissection alone or in conjunction with the primary cancer in the head and neck region. The basic biological facts of the behavior of cancer in the head and neck have given authenticity to this method of management. Approximately ninety per cent of the cases of cancer in Stage I-II are localized in a specific region of the head and neck. Failure of cure in these instances is essentially failure of control of the primary cancer or the regional cervical metastases. The successful application of an investment type of composite resection has proven to be one of the most important advances in the management of extensive cancers with obvious lymph-node involvement and supersedes all other types of treatment in a primary effort for cure.

The application of the elective radical neck dissection in the absence of gross metastasis requires considerable prudence; the size of the primary cancer, as well as the anaplastic and invasive characteristics and the metastatic potential of the primary cancer give some justification for the procedure. However, the general application of radical neck dissection has no justification in the management of all primary cancers in the region of the head and neck. The success of such radical neck dissection is borne out by an overall cure rate of approximately twenty-five per cent in cases with proven positive nodes.

Bronchogenic Carcinoma

PAUL H. HOLINGER, M.D.*
Chicago, Illinois

THERE ARE FEW pathologic entities which have been as startling and as ominous as the increased incidence of bronchogenic carcinoma in this generation. From a condition of some medical rarity to the second most common cause of cancer death in men has been its course in the past 35 years. Aside from certain well known and documented exposures to inhalants of various types of radioactive carcinogens, the one factor that can be attributed to this alarming problem is its relation to cigarette smoking.

Diagnostic Bronchoscopy

The diagnosis of bronchogenic carcinoma rests on obtaining representative tissue or cells from which the pathologist can establish the presence of cancer cells and, when possible, the morphology of a tumor. This is the responsibility of the bronchoscopist, who in many instances is an otolaryngologist. In bronchogenic carcinoma this procedure is accomplished by direct vision biopsy, by fluoroscopically guided bronchoscopic forceps biopsy, by random bronchial biopsy, and by various techniques of bronchial washings. Random bronchial biopsy may include tissue from the bronchial wall and, on occasion, has established a diagnosis by direct intra-bronchial lung biopsy. Cytology collection techniques are made more productive by collecting sputum samples during the cough associated with the administration of the tracheobronchial anesthetic prior to a bronchoscopy and four additional samples immediately following bronchoscopy. Accuracy in regard to site of involvement is improved by collecting individual specimens from the separate sides or even the individual bronchial segments. For better recognition of the morphology, secretions collected directly in centrifuge tubes and subsequently completely processed in the same tube avoiding loss of tissue fragments further improves the "take."

*Professor of Bronchoesophagology, Department of Otolaryngology, University of Illinois, College of Medicine, Chicago.

Preoperative Bronchoscopy

These numerous procedures to improve the pre-surgical accuracy of diagnosis have been used for many years. Nevertheless, some of them are unnecessarily complicated and tend to prolong the definitive preoperative diagnostic time. The ease and simplicity of exploratory thoracotomy justifiably made it more expedient, in certain instances, to bypass some of these steps. Recently, however, two new therapeutic procedures have re-emphasized the importance of these steps. The first is the therapeutic effectiveness of cobalt radiation and the second is the conservation of lung tissue through limited resection and sleeve anastomotic technics. Both depend on highly accurate pre- and post-irradiation biopsy, and thus to pre-surgical bronchoscopic evaluation of tumor involvement.

A careful preoperative bronchoscopic evaluation is essential to determine the nature of the tumor, its upward extent along the bronchial or tracheal wall, and the character of the bronchi distal to the tumor site.

Preoperative bronchoscopy and, occasionally bronchography, suggest the site of tumor invasion as well as the character of the bronchial pattern and lung tissue beyond.

Surgical Procedures

Most of the surgical procedures fall into one of five categories. (1) Tracheal sleeve: resection of a segment of trachea (three rings); direct anastomosis of the proximal and distal edges. (2) Right upper lobe sleeve: resection of the right upper lobe and right bronchus adjacent to the upper lobe orifice; anastomosis of the intermediate to the right main bronchus. (3) Left upper lobe sleeve: resection of the left upper lobe and left bronchus adjacent to the upper lobe orifice; anastomosis of the left lower lobe bronchus to the left main bronchus. (4) Left

lower lobe sleeve: resection of the left main and left upper lobe bronchi, removing the left lower lobe; anastomosis of the left upper lobe bronchus to the left main bronchus. (5) Pneumonectomy and sleeve: resection of the right lung, carina and distal trachea; anastomosis of the left main bronchus to the trachea.

Postoperative Bronchoscopy

Twenty-four hours after surgery, physical and x-ray findings are obtained to evaluate the patency of the sleeve. Bronchoscopic aspiration is performed if rales, an absence of breath sounds, dullness or atelectasis is demonstrated. Mucosal edema, an irregular, firm suture line, a kinked bronchus, or the presence of secretions that the patient cannot raise through the site of anastomosis are observed. These findings necessitate thorough aspiration of secretions and gentle dilatation of the anastomosis. Thereafter, bronchoscopic aspirations are repeated, daily if necessary, until the lumen remains adequate for drainage and aeration. After the first week, granulation tissue develops in some patients which requires forceps removal to maintain an adequate lumen. Sutures within the bronchial lumen are obvious from the first postoperative examination. Silk sutures, 4-0 or 5-0, have been used, the knots all tied extralumenally; but after the first week or two the knots and suture ends are found intralumenally when they may be cautiously removed with bronchoscopic forceps. Granulation tissue may continue to form until all visible sutures have been removed. There has been little or no such reaction with newer plastic suture materials. Eventual healing is accompanied by varying degrees of scar tissue stenosis that requires occasional bronchoscopic dilatation. If hemoptysis occurs, a bronchoscopic examination is made to determine if further sutures or granulations are present or if hemoptysis is an indication of recurrence.

Advanced Laryngeal and Laryngopharyngeal Cancer

Combined
X-ray
Therapy
and
Surgery

JOSEPH L. GOLDMAN, M.D.*
New York, New York

SINCE BILLROTH performed the first laryngectomy in 1873, the treatment of cancer of the larynx has been influenced by a variety of concepts, purposes, and progressive developments concerned with improvement of results. The introduction of the fractional method of radiation by Coutard in the 1920s as a modality to treat laryngeal cancer made a second method of therapy available. Since then, both surgery and radiation have proved successful in varying degrees in the treatment of cancer of the larynx. The size and location of the lesion together with the presence or absence of metastases to cervical lymph nodes have been the decisive factors which have tested the effectiveness of both modalities. The treatment of cancer of the larynx has raised functional considerations, particularly in the form of radiation therapy, partial procedures and radical neck dissection. It has been our contention that patient survival should be the prime consideration, but question exists whether complete evidence is available for all decisions.

So far, surgery or radiation separately has yielded poor results for advanced laryngeal and laryngopharyngeal cancers, and these lesions still remain a challenge to the laryngologists. It is our belief that the best opportunity for survival can be obtained by combining radiation and surgery in a unified plan for the treatment of advanced laryngeal and laryngopharyngeal cancers and metastatic lymph nodes. Combined therapy must be regarded as an uncompromising single approach, and it should be emphasized that combined therapy is not the same as instituting surgery months later, after radiation therapy has failed. Under such circumstances, the surgeon is dealing with a new generation of cancer cells and with the later post-radiation problem of fibrosis and obliterative endarteritis which

*Professor and Chairman, Department of Otolaryngology, Mount Sinai School of Medicine.

seriously affects healing. We should like to submit this form of combined x-ray therapy and surgery as an evolutionary development in the treatment of advanced laryngeal and laryngopharyngeal lesions.

Treatment at Mount Sinai

A specific program of combined radiation and surgical therapy for advanced carcinoma of the larynx and laryngopharynx was started in the Department of Otolaryngology at The Mount Sinai Hospital in 1958. Included in this program were patients who could be classified as Stage III as determined by the VIIth International Congress of Cancer. Reclassifying the 37 patients according to the criteria of The American Joint Committee on Cancer Staging and End Results Reporting, it was found that 19 belonged in Stage IV, nine in Stage III and nine in Stage II.

The treatment program is a predetermined plan which involves three phases. First, 5500 rads tumor dose of cobalt 60 is administered to the primary tumor and neck nodes via parallel opposed ports in five to six weeks. Second, there should be an inter-

val waiting period of three to six weeks after the end of therapy to allow the radiation reaction to subside. Third, the surgical procedure, consisting of wide-field laryngectomy, ipsilateral hemithyroidectomy and radical neck dissection is performed.

Results

In this report the statistics studied up to April 1, 1966, will be presented. Thirty-seven patients were treated, and 19 of 25 were living and free from disease for periods ranging from two to seven years (Table 1). The survival rate for two years was 76%, for three years 74%. The available literature indicates that the difference between the two and five-year survival rates of these cancers treated with radiation is only 10%. Since the expected survival rates of these advanced cancers treated with either radiation or surgery alone range from 10% to 40%, we believe that the combined therapy approach will at least double the survival figure for laryngeal and laryngopharyngeal cancer in the category indicated.

Examination of Specimens

As a result of the clinical effectiveness of this program, a histopathologic study of resected laryngeal and neck specimens was undertaken in 1961 in order to determine precisely the effect of radiation. We studied in detail, using en-bloc serial sections, the location of residual tumor nests and the manner in which cancer cells regressed and were destroyed.

Residual Tumor Nests

The size of the residual tumor nests that frequently were found in the larynges is of major importance. In five cases there were several tumor nests 0.5 millimeters or less in diameter. Two cases contained solitary tumor nodules between 0.8 and 1 millimeter in diameter. In the remaining larynx studied there was a single focus 1 × 1.5 centimeters in size. It became apparent then that in most cases the response to 5500 rads of teletherapy is such that the tumor regresses into tiny nests, distributed at random in the tumor bed.

TABLE

In the hands of many clinicians, teletherapy in the dose range of 5000-7000 rads is given as the primary treatment modality, and the patient is subjected to operation only if the lesion fails to respond to radiotherapy or if there is evidence of recurrence of neoplasm on mirror laryngoscopy some time after the end of the radiation treatment. It is our contention that the small size of the tumor remnants usually found after radiotherapy makes clinical evaluation of residual tumor very difficult or perhaps impossible for even the most experienced clinician. We also feel that the practice of doing random biopsies on an irradiated larynx carries with it only a small chance of finding these minute nests. We have seen cancer subjacent to intact mucous membrane both lying free in the subcutaneous tissues (Figure 1) and in the lymphatics. The most diligent follow-up examinations of these patients would fail to reveal the presence of these foci. These findings seriously question the practice of treating advanced cancer of the larynx with therapeutic levels

Fig. 2 — Nest of cancer cells (A) 1.5 cm. distant from mucosal surface.

Fig. 1 — Cancer focus (A) in subcutaneous tissue beneath intact mucous membrane.

of radiation and operating only after the clinical appearance of residual carcinoma.

Another principle which has become clear as a result of our studies is that it is essential to remove the same volume of tissue which would have been excised if surgery had been the sole modality of treatment. If carcinoma were to undergo a centripetal regression as its response to therapeutic levels of irradiation, it would be possible to do a less extensive resection after radiotherapy. On the contrary, we have seen nests of tumor cells distant from the mucosal surface presumed to be the origin of the neoplasm (Figure 2). The locations of the residual cancer follow no discernible pattern and can lie anywhere in the area previously occupied by tumor.

Serial studies of irradiated neck specimens, inaugurated later in our program, promise to yield valuable information. Of three neck specimens which were considered positive before and after radiation, two were found to be free from cancer. In another specimen, all nodes palpable before radiation showed no evidence of cancer after radiation, but a small lymph node, four millimeters long, which was not palpated before radiation, exhibited cancer after radiation. It seems warranted to conclude that radiotherapy can in some cases sterilize cancer in cervical lymph nodes, even if the nodes remain palpable after treatment.

Discussion

The use of combined therapy for the treatment of cancer is not new. Our ideas were influenced by European laryngologists who advocated radiation therapy before and after surgery, the so-called sandwich method, for cancer of the larynx. However, we feel that the full benefit of a combined program cannot be realized by reducing the preoperative radiation by one half and radiating a large volume of tissue after surgery. It is our concept that the disease itself should be treated as thoroughly as possible before extirpation. Although preoperative radiation in the treatment of laryngeal cancer has not been used before in the way that we have

suggested, it has been employed in attacking cancer of the maxilla, lung, esophagus, endometrium, cervix, breast, colon, rectum and bladder.

It was natural that we were drawn to some form of combined therapy in view of our favorable experiences with radiation therapy for carcinoma of the larynx. The decision to use 5500 rads preoperatively was empiric, yet influenced by experience and carefully considered judgment. It was our desire to use a biologically effective radiotherapeutic dose which would not interfere with the performance of surgery. In general, it seemed reasonable that the largest effective dose that would permit satisfactory performance of the required surgery and produce the highest survival rate would be the method of choice.

The chief concern about preoperative radiation has been the anticipated influence on ensuing surgical procedures. Complications have been frequent in our series because of the influence of irradiated tissues, but even this consideration has been difficult to judge clearly on a comparative basis. It should be realized that we have treated very extensive laryngopharyngeal lesions which required wide resections and presented difficult closures; nevertheless, the end results have been much better than previously reported for advanced laryngeal and laryngopharyngeal lesions, and all complications have been successfully treated.

Another question which has been raised in relation to this program has been the possible removal of cured larynges and radical neck specimens. It has been established that a certain small percentage of laryngopharyngeal cancers can be cured by radiotherapy; thus inevitably there will be such cases in our series. It has been our contention that it is impossible to determine whether larynges or associated neck tissues are free from disease by visual examination, biopsy, or palpation, and this has been supported by our study. The success of the combined therapy plan to achieve improved total results depends on an uncompromising policy.

Life is the art of drawing sufficient conclusions from insufficient premises. — Samuel Butler

Neoplasia of the Parotid Gland

Surgical Management

FRANK D. LATHROP, M.D.*
Boston, Massachusetts

SURGICAL MANAGEMENT of parotid tumors, if it is to be considered adequate, should consist of the complete removal of the neoplastic disease with as little damage to adjacent normal structures as compatible with its accomplishment. Ideally, adequate excision has been accomplished when the excised neoplasm is surrounded completely by grossly normal appearing tissue at least 1 cm. thick. The extent to which this ideal can be attained, however, will be governed to an appreciable degree by the location of the tumor within the gland, its size, and the pathologic nature of the neoplasm.

Preoperative Evaluation

Physical Examination

Although malignant neoplasia of the parotid gland occurs less frequently than benign neoplasia, any tumor of this gland should be considered malignant until proved otherwise. Clinical examination may suggest that the neoplastic process is benign or malignant. The former is suggested by a slow rate of growth without associated pain, fixation, or facial paralysis, whereas more often a malignant process is associated with an increased growth rate, pain, fixation to adjacent structures, facial paralysis, and occasionally ulceration.

Special Studies

Diagnostic aids such as sialography and needle biopsy may be helpful in evaluating the pathologic process. Sialography often permits differentiation of neoplastic and inflammatory conditions of the parotid gland and, on occasion, may aid in distinguishing a benign from a malignant lesion. Needle biopsy may help in crystallizing an opinion concerning the nature of the pathologic process in doubtful cases. The interpretation of such biopsy material is difficult, however,

*Emeritus Head of Department of Otolaryngology, Lahey Clinic Foundation and Otolaryngologist, New England Deaconess Hospital and New England Baptist Hospital.

and as a result precise identification of the pathologic process involving the gland may not be possible. Its greatest value probably is in differentiating chronic inflammatory disease simulating tumor formation from true neoplasia of the parotid gland.

Frozen Section Examination

The true nature of the neoplasm, however, cannot be ascertained until final histologic examination has been completed by a competent pathologist. For this reason, permission should be obtained from the patient before definitive surgical intervention is instituted to permit any procedure deemed by the surgeon necessary to eradicate the disease. Frozen section examination during the course of the operation is helpful in determining the nature of the neoplasm and the extent of the resection necessary to eliminate it. However, such examinations are not infallible. On occasion, the frozen section diagnosis may not be compatible with the surgeon's opinion of the tumor when that opinion is based on extensive surgical experience with neoplasia of the parotid gland. In such instances, it is probably wiser to depend upon the surgeon's experience rather than on the laboratory report.

Benign Tumors

Benign tumors of salivary gland origin are classified as mixed tumor, Warthin's tumor or papillary cystadenoma lymphomatosum, muco-epidermoid tumor, and adenoma. The mixed tumor is by far the most common tumor found in the parotid gland. Next in order of frequency are Warthin's tumor, muco-epidermoid tumor, and the varieties of adenomas.

Permanent paralysis of the face is the most dreaded complication of any operation upon the parotid gland. As a result, the neoplastic process may be inadequately removed when fear of producing a facial palsy plays a dominant role in the surgical management of such lesions. Yet this should not be so. The facial nerve lends itself admirably to the adequate surgical removal of benign neoplasms of the parotid gland, for it affords a plane of dissection which can be followed

so that the superficial lobe of the gland and any tumor contained therein can be removed intact. Since many benign neoplasms are situated in the superficial portion of the parotid gland, superficial lobectomy is the surgical procedure of choice for the management of such lesions. If the dissection is carefully performed, permanent paralysis of the face should not occur.

Deep Lobe Tumors

A tumor arising in the deep lobe of the parotid gland may pose problems in its removal because it is situated beneath the facial nerve. The superficial lobe of the gland must first be removed so that the relationship between the tumor and the facial nerve can be observed. If the tumor is small, it may be possible to mobilize the facial nerve sufficiently so that it may be retracted gently in one direction or another and the tumor thus removed intact without significant injury to the facial nerve. If this is not possible because of the size of the tumor, the mobilized branches of the facial nerve should be retracted in an appropriate direction and the segment of the nerve that prevents removal of the tumor sectioned. The continuity of the sectioned portion may then be reestablished by neurorrhaphy. Whenever possible, it is preferable to section those branches originating from the cervicofacial division of the facial nerve, as paralysis of the corner of the mouth or lower lip is much less distressing to a patient than is paralysis of the eyelids. Large tumors of the deep lobe may extend deeply into the pharyngomaxillary space. When this occurs, osteotomy of the body of the mandible may be necessary so that the surgical field can be enlarged sufficiently to permit the tumor to be delivered intact. If the continuity of the mandible is reestablished by wire sutures placed in a crisscross manner through drill holes on either side of the osteotomy, the patient will incur no appreciable disability.

On rare occasions, the facial nerve may become incorporated in recurrent mixed tumors. When this is found to be the case during operation, no attempt should be made to preserve the integrity of the nerve.

Rather, the recurrent tumor and that portion of the facial nerve incorporated in it should be excised so as to prevent contamination of the surgical field by tumor cells, which would occur if any attempt were made to remove the facial nerve from the substance of the tumor. The defect in the facial nerve can then be repaired by an autogenous nerve graft with subsequent improvement in the facial paralysis.

Malignant Tumors

The satisfactory management of malignant disease of the parotid gland is much more difficult than is that of benign tumors. Although the fundamental principles of surgical treatment are essentially the same for both benign and malignant neoplasia except that less attention is paid to preservation of the facial nerve when the tumor is malignant, difficult decisions must be made by the surgeon relative to the extent of the excision necessary to eradicate the disease when the tumor is malignant. Ideally, wide excision with sacrifice of the facial nerve is indicated in all cases. However, there is wide variation in the clinical behavior of the various types of malignant neoplastic disease involving the parotid gland and, to some extent, this influences the surgeon's decision as to whether the facial nerve in any particular instance should be preserved or sacrificed either in part or in its entirety. It should be realized, however, that the surgeon carries a heavy burden of responsibility when he preserves the facial nerve in the presence of a malignant tumor.

Malignant neoplasia of salivary gland origin may be classified as malignant mixed tumor, muco-epidermoid carcinoma, adenocarcinoma, epidermoid carcinoma, and undifferentiated carcinoma. The last three exhibit more of the stigmata of malignancy than do malignant mixed tumors or muco-epidermoid carcinoma.

Adenocarcinoma

Adenocarcinoma is the malignant neoplasm of the parotid gland most often encountered, and one of its variants, the

pseudoadenomatous basal cell carcinoma, carries a grave prognosis. This is because clinically it resembles a benign lesion in many instances and as a result is often inadequately removed. For this reason, when this tumor is suspected before operation, total parotidectomy with preservation of the facial nerve, when the latter is not involved in the malignant process, is the surgical treatment of choice. If the suspected diagnosis is confirmed by histologic examination, postoperative radiation therapy may be advisable, since evidence is accumulating that this tumor exhibits some degree of radiosensitivity.

The malignant nature of small tumors confined to the superficial lobe of the parotid gland may not be realized until the pathologic report has been received. Not infrequently, such malignant tumors have been adequately excised by superficial lobectomy. Under such circumstances nothing more need be done.

Facial Nerve

When exposure of the parotid gland reveals that it is involved in an infiltrative malignant process, even though facial palsy is absent, the lesion must be widely excised if a cure is to be expected. Under such circumstances the decision as to whether total parotidectomy should be combined with total or only partial sacrifice of the facial nerve will rest with the surgeon. Not all malignant tumors require complete sacrifice of the facial nerve. Malignant mixed tumors and muco-epidermoid carcinoma do not exhibit a high degree of malignancy as a rule and frequently can be adequately excised with resection of only that portion of the facial nerve involved in the tumor. However, when the malignant disease exhibits evidence of local invasion or lymphogenous spread manifested by preoperative facial paralysis and involvement of regional lymph nodes, more radical measures should be instituted. This involvement occurs most frequently with epidermoid and undifferentiated carcinoma of the parotid gland. In general, in such instances the operation should consist of total parotidectomy with sacrifice of

the facial nerve combined with radical resection of the cervical lymph nodes in continuity.

Discussion

Benign neoplasia of the parotid gland occurs with much greater frequency than does malignant disease. The surgical management of primary benign tumors of the parotid gland situated in the superficial lobe of the gland should pose no serious problems if they are completely removed at the initial operation. This is usually accomplished when superficial lobectomy has been performed. This procedure may not permit the inclusion of a border of normal parotid tissue on the medial aspect of a large tumor because the tumor capsule lies adjacent to the facial nerve. In benign encapsulated tumors, the facial nerve should be preserved unless the tumor is so situated in the deep lobe of the gland that section of a portion of the nerve is necessary to remove the tumor. The continuity of the sectioned nerve is then reestablished by neurorrhaphy.

Recurrent Tumors

Recurrent benign tumors pose a more difficult problem of management. Recurrence develops because initially the tumor was inadequately removed. As a result, the integrity of the facial nerve is placed in greater jeopardy when operating on recurrent tumors. Whenever compatible with adequate removal of the recurrent tumor, the facial nerve should be spared. If this is not possible, however, the portion of the facial nerve that prevents adequate removal should be excised and the continuity of the nerve reestablished by an autogenous nerve graft.

Immediate Nerve Graft

Although malignant neoplasia of the parotid gland occurs less frequently than does benign neoplasia, the management of malignant tumors is much more difficult and less satisfactory. The fundamental principle of adequate surgical excision still applies but, of necessity, less attention is paid to maintaining the integrity of the facial nerve. Sacrifice of the facial nerve is not necessary

in every instance for adequate excision of the malignant disease. When the facial nerve has been sacrificed to an extent that significant paralysis of the face results, it should be alleviated by autogenous nerve grafting rather than depending upon the hit-or-miss proposition that spontaneous recovery may occur.

Neck Dissection

When preoperative facial paralysis or cervical lymphadenopathy is indicative of local invasion and lymphogenous spread of the malignant process the surgeon has no alternative. In such instances, total parotidectomy, sacrifice of the facial nerve, and radical neck dissection are mandatory.

Radiation Therapy

The role of roentgen therapy in the management of malignant disease of the parotid gland has not been established. As the primary form of treatment for malignant neoplasia of the parotid gland of salivary gland origin, it has not proved as effective as has surgical intervention.

Surgical Judgment

The ideal treatment might be formulated but this does not mean that deviations from it necessarily indicate inadequate surgery has been performed or that the surgeon has not operated in the best interest of the patient. For example, diagnosis of a frozen section is helpful during surgical excision of a neoplasm in determining whether the tumor is benign or malignant and in obtaining adequate borders of excision. However, such diagnoses are not infallible. When the neoplastic process appears to be malignant in the judgment of the surgeon and the frozen section diagnosis indicates that it is benign, reliance is best placed on the surgeon's impression. In another instance, even though he realizes that residual tumor may be adherent to the facial nerve after the tumor has been excised, the surgeon may consider it more humane to forego sacrifice of the nerve in order that the patient may be spared the catastrophe of permanent paralysis of the face.

The Assessment of Vertigo

W. J. McNALLY, M.D.*
Montreal, Canada

VERTIGO OR DIZZINESS occurs when conflicting information from the sense organs, ordinarily concerned with balance, reaches consciousness. It is the resulting confusion which gives rise to the sensation of vertigo. The sensory mechanisms concerned with balance are visual, kinesthetic and labyrinthine. Adler (1941) has stated that ocular vertigo is never very severe. Cawthorne (1964) has made the statement that he has never seen a case of vertigo which could have been attributed to an ocular disorder.

Patients Description

Alpers (1941) stated that with central lesions, a patient's description of vertigo is vague and the patient finds it difficult, even with help, to define the nature of the sensations, whereas the patient with labyrinthine vertigo has no such difficulty. On the other hand, McNally and Stuart (1941) analysed the sensations which followed caloric stimulation of the labyrinth in a number of individuals. Many of the patients did not experience any sensation of rotation, and a large number of them did have difficulty in describing their sensation. Some said that it was a feeling of "going to faint," others a "swimming sensation"; yet others described it as a "weakness." A rotatory sensation may be the result of peripheral labyrinthine stimulation, but Alpers has found that it may also be present in lesions within the central nervous system.

Vertigo and Nystagmus

Jones (1918) pointed out that when rotatory vertigo results, following labyrinthine stimulation, the turning sensation is in the direction of the quick phase of nystagmus; whereas past-pointing and falling are in the direction of the slow phase.

In general, it is the nystagmus which is used as an index of labyrinthine reaction. On

*Consulting Otolaryngologist, Institute of Otolaryngology, McGill University and the Royal Victoria Hospital, Montreal.

the other hand, Van Egmond, Groën and Jongkees (1948) stressed the importance of also recording the time of onset and duration of the after-turning sensations. The test which they named Cupulometry consists of minimal rotatory stimulation with recording of not only the nystagmus but also the after-turning sensations. It is still very much a laboratory, rather than a clinical, test.

Etiology

As to the cause of vertigo or its source of origin, Cawthorne (1957 and 1959) stated that in his personal experience of more than 2500 patients suffering from vertigo, the cause lay within the labyrinth or the peripheral vestibular neurons in 85% of cases and within the central nervous system in only 8%. He quoted Gower as having stated that in 106 consecutive cases of vertigo there were ear symptoms present in no less than 94% of the cases. Kase et al. (1965) report finding the complaint of dizziness in 820 of a series of 23,062 outpatients. In this series hypertension was present in 21.3% of the patients suffering from vertigo, and cerebral vascular disease in another 10.5%. They diagnosed Ménière's disease in only 8% of the cases.

Labyrinthine vs. Psychological

Labyrinthine vertigo is frequently associated with nausea and vomiting and there may or may not be headaches. Busis (1965) states that if nausea and vomiting precede the vertigo, or if vomiting occurs without nausea, the lesion is probably not of labyrinthine origin. If the vertigo is continuous, a functional etiology should be considered. Brain (1962), when discussing possible causes of vertigo, concludes with the following warning: "In all cases of giddiness (vertigo), however great the psychological factor, investigate the labyrinth; in all cases of giddiness, however great the organic factor, never forget the psychological reactions."

The association of deafness with vertigo suggests that the lesion may be in the peripheral end-organ, but this association does not exclude the possibility of central

nervous system disease.

Loss of Consciousness

The relationship of loss of consciousness to vertigo has led to a considerable amount of confusion and difference of opinion. In my experience, if there is a genuine loss of consciousness, a thorough neurological investigation has usually confirmed the presence of a central nervous system lesion. On the other hand, Riesco MacClure cites a case in his lecture series of 1958, in which there was vertigo with the patient losing consciousness for thirty minutes; yet the case is classified as one of bilateral Ménière's syndrome. It is hard to imagine how loss of consciousness can result from any lesion confined within the peripheral labyrinth.

Organic Disease

The occurrence of vertigo in the course of suppurative middle ear disease is of particular importance, because of the possibility that it indicates an imminent internal ear involvement.

When one is confronted with a patient complaining of vertigo, one should think of the general medical causes of such a symptom. Viral infection is regarded as a common cause but difficult to confirm. Vascular changes are probably the most common, such as arteriosclerotic changes in older persons, cardiac disease, vascular spasm in middle-aged individuals (I would say extremely common), small apoplectic central nervous system lesions, vertebral artery disease or compression of the vertebral artery due to cervical spinal disease.

Lesions

Above Entrance of Eighth Nerve

Lesions within the brain stem, particularly posterior-inferior cerebellar artery occlusion, must be considered. Carmichael, Dix and Hallpike (1965) have classified this latter lesion under two headings. They point out that the cochlear nuclei are all above the level of entrance of the eighth nerve, whereas the vestibular nuclei extend both above and below this level. If vertigo and

loss of hearing are prominent symptoms, this would suggest that the lesion is above the level of entrance of the eighth nerve; whereas, if there is no hearing loss, it would suggest that the lesion is below the level of the eighth nerve. For each of these areas they point out additional symptoms which help in localizing the lesion.

Lesions above the entrance of the eighth nerve are likely to be accompanied by abducens and facial paresis and widespread disturbance of trigeminal sensory function.

Below Entrance of Eighth Nerve

Lesions below this level are likely to give rise to disturbance of painful perception over the opposite half of the body and the territory of the first division of the ipsilateral fifth nerve, incoordination of the ipsilateral limbs, and paresis of the ipsilateral vocal cord and half of the soft palate. With still more caudal lesions there may be sensory changes in the ipsilateral upper limbs.

Miscellaneous Causes

More generalized central nervous system lesions, such as disseminated sclerosis, are also possible causes. Post-traumatic vertigo is a very well known phenomenon. Ophthalmological disease causing vertigo has already been mentioned. Biliary disease is a common cause of vertigo. The various drugs which can affect the labyrinth and cause vertigo, such as streptomycin, very readily come to mind as well as some of the other antibiotics such as Kanamycin.

Sensori-Neural vs. Cochleo-Vestibular Involvement

Hallpike and his group have stressed the importance of differentiating between the two more important types of sensori-neural, cochleo-vestibular involvement — the one being due to end-organ or hair-cell disease as in Ménière's disease and the other due to nerve fibre disease, as in eighth nerve tumor.

The fundamental finding common to both groups is bone conduction loss, and if the loss is unilateral, careful masking of the normal ear must be carried out.

End-organ Disease

In cases of end-organ disease, such as Ménière's disease, caloric responses may be normal between attacks, but they have been reported as abnormal in as many as 90% of cases by Carmichael, Dix and Hallpike. These latter found unilateral canal paresis, directional preponderance (which they ascribe to utricular disease), or a combination of both. They stated that spontaneous nystagmus is common during attacks, but that positional nystagmus is rare. These same workers have shown that the tests for hearing function are even more diagnostic in Ménière's disease than are the vestibular findings. There is usually a low tone sensori-neural fluctuating type of deafness. Speech discrimination is generally poor, loudness recruitment is always present, the Short Increment Sensitivity Index test is usually positive. Békésy audiometry tracings are usually Type I or Type II.

Nerve Fibre Disease

In the case of nerve fibre disease, such as in eighth nerve tumour, Carmichael et al. report finding abnormal vestibular reactions in 100% of their cases. According to them, positional nystagmus is rare. House (1964), reporting on his findings in early cases of eighth nerve tumour, states that if caloric reactions are normal it is very strong evidence that neither the labyrinth nor the vestibular nerve is the cause of the symptoms. He further emphasized that if there is involvement of the fifth and seventh nerves it is no longer an early case.

In nerve fibre disease, the sensori-neural hearing loss is typically of the high tone variety. Speech discrimination may be good or poor. Loudness recruitment is usually absent. The Short Increment Sensitivity Index test is as a rule poor. The Békésy audiometry may reveal tone decay as in Type III tracings, but Type II and Type IV tracings have been reported. House regards radiography in combination with radiopaque material as a most important diagnostic measure for early eighth nerve tumor.

The chapter on the diagnosis and treatment of acoustic neuroma will deal with the above matters in detail and will show how

House's translabyrinthine approach to the internal auditory meatus has emphasized the importance of early diagnosis.

Benign Paroxysmal Positional Nystagmus

Carmichael, Dix and Hallpike (1956) have classified another group of cases of possible end-organ disease under the term Benign Paroxysmal Positional Nystagmus. The term was first applied by Dix and Hallpike in 1952 to cases of vertigo which were found to show positional nystagmus — direction fixed and somewhat similar to Nylén's Type II. They consider these cases to be probably the result of otolithic disease. The caloric tests are often normal and there is frequently associated middle-ear disease, and in such cases there may be hearing loss.

The cause of the condition is thought to be trauma, low grade infection or vascular occlusion. Neurological abnormalities beyond the eighth nerve system are conspicuously absent. Some histological evidence has been put forward to support the idea that in these cases the lesion is in the utricle. However, Nylén has pointed out that in the histological evidence presented there were also lesions in other parts of the labyrinth and central nervous system. Some cases were reported in which destruction of one labyrinth eliminated the positional nystagmus.

However, Fernandez, Alzate and Lindsay (1959) found that a positional nystagmus which was present after a lesion in the nodulus of the cerebellum in cats, disappeared when the labyrinth on the same side was destroyed. This would indicate that disappearance of the positional nystagmus after labyrinthectomy does not prove that the causative lesion was confined to the peripheral end-organ in the above mentioned cases of Dix and Hallpike.

Vestibular Neuronitis

Carmichael, Dix and Hallpike have also described another group of cases in the nerve fibre disease class. To these cases they have given the term Vestibular Neuronitis. The vestibular reactions are abnormal in 100%. There is no positional nystagmus, and cochlear symptoms and signs are absent. The on-

set of the symptoms is frequently associated with infective illness. The clinical course is essentially benign. The pathological basis of this vestibular disorder still is a matter of conjecture. Because the galvanic test reactions were diminished in some cases it was thought that the neurons might be damaged. There is no histopathological evidence of a neuronal lesion.

Positional Nystagmus

The finding of positional nystagmus is important in a patient complaining of vertigo. Nylén has described two types — Type 1 which changes direction with alteration in the position of the head and is more common in central lesions, and Type II which has a fixed direction and may indicate either a central or a peripheral lesion. It is a modification of this latter type which Hallpike has described as benign paroxysmal and which has already been discussed.

It is important to note that positional nystagmus is an objective sign of organic disease which may be situated in the central or peripheral vestibular mechanism. Its diagnostic and lateralizing significance has not been uniformly accepted. These matters will be discussed in more detail under the heading of Postural Vertigo.

Directional Preponderance

The matter of directional preponderance has been much discussed in the literature. Under the term Nystagmus Bereitschaft, it was reported by Dusser de Barenne and de Kleyn (1923) and by de Kleyn and Versteegh (1927) as an indication of cerebral hemisphere disease. The term refers to a tendency for nystagmus to be more readily elicited towards one side than toward the other. Hallpike and his group changed the term to directional preponderance and reported that the phenomenon resulted from a lesion in the temporal lobe, but not from other parts of the cerebrum. Other workers have reported directional preponderance from other cerebral areas, and it has been reported in as high as 20% of normal individuals. De Kleyn and Versteegh (1933) reported directional preponderance in

Ménière's disease, and Fitzgerald and Hallpike (1942) reported its presence in Ménière's disease and in other labyrinthine lesions which they ascribed to the otoliths, especially to disease of the utricle. Hamersma (1957) believes that a directional preponderance is essentially a spontaneous nystagmus which has remained latent.

Jongkees and Philipszoon (1964) conclude from their study that in cases of Ménière's disease, postradical ear surgery, suppurative otitis media, brain tumours, the finding of spontaneous nystagmus, positional nystagmus and directional preponderance are not lateralizing diagnostic signs.

Electronystagmography

The possibility of making a nystagmogram or record of a patient's nystagmus has been a great step forward in the study and analysis of vertigo. Many important studies have been published which have contributed greatly to the interpretation of nystagmograms. It has been repeatedly emphasized that possibilities for misunderstanding and for outright error are many, unless each test is carried out with the utmost care being given to every detail.

Also, it has been stressed how important it is to record every single detail of the test on each particular occasion. The apparatus used must be described, eye movements must be calibrated, the electrodes must be positioned with great care (a loose connection will alter the record), the conditions under which the test is done — a relaxed or nervous patient, a drowsy or alert patient, a noisy or quiet room, a bright or darkened room, with eyes open or closed, with or without Frenzel's glasses: all these details must be noted.

The interpretation of the nystagmogram must be made by a physician skilled in otoneurology.

Recapitulation

The most important steps in the establishment of a diagnosis of the cause of vertigo are a thorough detailed history and a careful physical examination, both local and general.

The examination of the ears, nose and throat should be complete, including catheterization of the eustachian tubes. A thorough inspection of the ear drums should be made to exclude the possibility of a small perforation. If there is any evidence of middle ear suppuration, a fistula test should be done at the very first session of the examination to exclude the possibility of threatened internal ear involvement, as has already been mentioned.

An assessment of hearing should be carried out and, of course, vestibular examination must be carefully done.

Before doing any active stimulation of the labyrinth, too much emphasis cannot be laid upon the importance of a search for spontaneous phenomena, such as spontaneous nystagmus and especially for positional nystagmus. Unfortunately, one cannot be absolutely sure about spontaneous nystagmus until nystagmography with eyes closed has been carried out. Furthermore, as has already been mentioned, the significance of directional preponderance is even more doubtful until such information is available.

One should also look for cranial nerve involvement — e.g., corneal reflexes, etc., and for any sign of cerebellar disturbance.

The most readily applicable office test is some form of cold caloric stimulation of the ears. One of the simplest and yet quite satisfactory is cold air douching by means of a Dundas Grant coiled tube and ethyl chloride.

If any abnormality or asymmetry is detected, the more complicated alternate hot and cold caloric stimulation with nystagmography should be carried out. This latter examination is now available in most clinics, especially those associated with postgraduate teaching.

In this short review, treatment has not been considered. It must be stressed that medical treatment should be exhaustively tried before surgical treatment is recommended.

Because remission of symptoms is so common in many of the conditions causing vertigo, the possibility of a remission must be considered when assessing the value of any special therapeutic measure.

The Episodic Vertigoes

HENRY L. WILLIAMS, M.D.*
Minneapolis, Minnesota

THERE IS NO one whom the otologist would more delight to honor than M. Prosper Meniere.

He was the first physician, and an otologist, to attempt a more orderly classification of the vertigoes, which up to his day had been lumped under the classification of "congestive accidents of the brain."

Meniere's Disease

He called attention to a group of patients with episodic vertigo whose cardinal distinguishing feature was a bass type hearing loss in one ear. He also suggested that the origin of the hearing loss (and the associated vertigo) lay in the labyrinth of the affected ear, which made him the first physician to apply to clinical medicine lessons learned in the physiologic laboratory. This type of episodic vertigo was accordingly called Meniere's disease.

However, in 1917, G. E. Shambaugh, apparently owing to difficulty translating Meniere's papers, proposed the term Meniere's syndrome to cover all types of vertigo, whether intermittent or steadily attenuating and from whatever cause. No attention was paid to Meniere's cardinal sign of unilateral sensori-neural type hearing loss.

The introduction of the term Meniere's syndrome" into the American literature not only undid all that Meniere had hoped to accomplish by separating a specific kind of intermittent vertigo from the general group of vertigoes of intracranial origin but increased confusion by lumping together vertigoes and dizziness not of intracranial origin with those that were.

In spite of the fact that the dictionary defines syndrome as a group of symptoms that tend to occur together but may be of diverse origin, and defines disease as a group

*Professor in Otolaryngology, Medical School, University of Minnesota; Chief, Otolaryngology Service, Veterans Administration Hospital, Minneapolis, Minnesota.

of symptoms and signs having a specific pathophysiologic origin, the term "Meniere's syndrome" rapidly gained popularity in the medical literature.

Meniere's syndrome and Meniere's disease are used as synonyms, and when this occurs the latter term becomes devoid of useful meaning. For this reason I believe that the term "Meniere's disease" should be abandoned in most instances and the term "the episodic vertigoes" substituted when a vertigo of short duration with a tendency toward intermittent recurrence is meant.

Episodic Vertigoes

If medical treatment is to be effective in controlling the symptoms of vertigo it must be directed at the cause. An etiologic diagnosis must at least be attempted.

Failure to obtain consistently favorable clinical results from treatment in the episodic vertigoes in all probability depends on the fact that having lumped them together under the term Meniere's syndrome, conditions of diverse etiology are subjected to a stereotyped method of treatment which in many instances should be considered illogical.

It must be granted, however, that differential diagnosis in the episodic vertigoes is rarely simple and easy, but rather is usually difficult and sometimes impossible by clinical examination or test.

Etiology

If this latter event proves to be the case it would seem reasonable to try to establish a working diagnosis of the etiology from the effects of various types of treatment.

It is illogical to follow too long a therapeutic approach which has proved disappointing. Another should be tried: one which may well be found effective on the basis of an etiology different from that primarily considered and subsequently found invalid.

If this plan is followed, most patients will receive such effective symptomatic relief from medical treatment that surgical intervention need never be considered.

There are many causes of intermittent

vertigo and many others which produce intermittent attacks of swimming in the head (or dizziness) which patients and many physicians confuse with vertigo.

Vertigo may be defined as an hallucination of motion of self or surrounding objects, while dizziness is defined as the sensation of something moving within the head.

Some of the conditions which might produce episodic vertigo are listed in the following table.

TABLE I
Causes of Episodic Vertigo
Otologic

1. Impacted cerumen.
2. Tubal occlusion with or without hypometabolic state.
3. Vasculitis involving internal auditory artery or vestibular emissary veins.
4. Hyper-irritable labyrinth.
5. Vertigo of labyrinthine destruction.
6. Post-traumatic vertigo (fracture or commotio labyrinthi)
7. Vestibular neuronitis.
8. Allergic reactions involving the labyrinth.
9. Senile degeneration of end organ.
10. Convulsive disorders involving the labyrinthine system (vestibular epilepsy, vertiginous epilepsy).
11. Migraine-like syndromes.
12. Meniere's disease.
13. Lermoyez's syndrome.
14. Sheehy's syndrome.
15. Ototoxic drugs.
16. Toxic effects and focal sensitization from infections of tonsils, adenoids, periapical tooth abscesses or sinuses.
17. Tumors of middle and inner ear.

Neurologic

1. Degenerating and demyelinating disease, especially multiple sclerosis.
2. Posterior fossa lesions.
 - a. Cystic arachnoiditis, syringobulbia, platybasia, Arnold-Chiari malformations, and fractures with involvement of substantia reticulata.
 - b. Neoplasms and subdural hematomas.
3. Supratentorial lesions with displacement of the brain stem.
4. Temporal lobe lesions with irritation of cortical areas.
5. Toxic infectious conditions.
 - a. Aseptic meningo-encephalitis.
 - b. Brain abscess.
 - c. Common viral diseases such as mumps, measles or whooping cough.
6. Vascular; including atherosclerosis, thrombosis, embolic occlusion and hemorrhage especially in fine vessels to the brain stem, the carotid and vertebral arteries.

Systemic

1. Cardiac disease.
2. Blood dyscrasias (anaemia, leukemia, lymphomas, polycythemia, purpura and reticulosis.)
3. Cogan's syndrome (non-syphilitic interstitial keratitis with vestibulo-cochlear symptoms — panvasculitis nodosa).

4. Hypertension (paroxysmal).
5. Hypotension (syncope).
6. Idiopathic paroxysmal hypoglycemia.
7. Cervical myalgia, arthritis and secondary fibrositis.
8. Addison's disease.

Ophthalmologic

1. Nonconcomitant strabismus.
2. Refractive errors.
3. Optokinetic vertigo.

Psychogenic

1. Tension — anxiety state.
2. Conversion reactions.
3. Neuroses (agoraphobia, claustrophobia).
4. Hyperventilation syndrome.

It would seem unreasonable to suppose that vertigo or dizziness arising from such diverse causes would respond to any single method of therapy, even if they were all categorized under the term "Meniere's syndrome" and the therapy was a centrally acting "antivertigo" drug.

Even if such medication gave symptomatic relief the physician would be derelict in his duty to his patient if he did not attempt an etiologic diagnosis.

Cervical Vertigo

Magnus pointed out that attitudinal reflexes are present in man and can be clearly seen under many pathological conditions.

Manifestations

It has been found, for instance, that the dysequilibrium of the inebriate is due to the fact that the attitudinal reflexes are depressed earlier and to a greater degree than the cortical functions by the ingestion of ethyl alcohol.

Magnus believed that the righting reflexes acted through reflex circuits to the utricular macula.

Travell described sudden vertiginous falling attacks which she believed acted through this mechanism. These seem to be similar, if not identical with the "utricular attacks" which Tumarkin ascribed to "Meniere's syndrome."

Gerlings observed that the head is often held to one side during an episode of "Meniere's syndrome" and suggested that the righting reflexes may sometimes be involved in this condition.

Cope and Ryan called attention to the fact that episodic vertigo may occur in cervical spondylosis and in cases of trauma involving the muscles and ligaments of the neck as in the so-called whiplash injury. It was their opinion that these lesions acted through the righting reflexes.

It would seem probable that a stimulus affecting the head or neck righting reflex is the most common cause of episodic vertigo.

Treatment

For episodic vertigo due to myalgia Travell found "trigger areas" in certain muscles, especially the sternomastoids. She found that spraying the tense muscle with ethyl chloride or injecting the relaxed muscle with a suitable anesthetic would abolish both the "trigger area" and the episodic vertigo.

In cervical episodic vertigo due to injuries to the cervical spine or ligaments Cope and Ryan stated that a well fitting cervical collar will give marked symptomatic relief.

Cervical traction has been highly recommended for cervical vertigo by some commentators.

Treatment should also be directed against the underlying or predisposing causes of cervical vertigo, such as hypoglycemia, ovarian dysfunction and the like.

Autonomic Dysfunction

Some observers believe that vertigo on the basis of autonomic dysfunction is the most common type. Mygind and Dederding pointed out that a great variety of autonomic stimuli might be reflected in stereotyped vascular reactions of a congenitally predisposed labyrinth. They found evidences of both vasodilation and vasoconstriction in the capillary beds of the labyrinth, neither seeming to predominate. It should be recalled that the autonomic nervous system does not produce vasomotion peripheral to the arteriole, the contractile elements of the metarteriole, precapillary sphincters and muscled venules being under autonomous control by vasoactive chemicals.

Manifestations

It would also seem proper to postulate autonomic stimuli to the fine vascular branches from the basilar artery which supply the longitudinal fasciculi and the vestibular nuclei as a cause of episodic vertigo.

The effect of such stimuli, in both labyrinth and brain stem, would be the production of intermittent vasospasm with anoxia, cellular injury, intravascular agglutination, increased vascular permeability, increase in interstitial fluid and release of toxic metabolites such as histamine, serotonin, or bradykinin.

Owing to the presence of vasoconstriction Davis suggested that it would be unreasonable to suppose that autonomic dysfunction affecting the labyrinth would result primarily in an endolymphatic hydrops as less, rather than more, endolymph should be secreted.

Seymour suggested that endolymphatic hydrops might result if a smaller quantity of an endolymph of increased osmotic pressure were secreted.

Vasodilators have been a popular remedy for intermittent vertigo on the presumed basis of autonomic dysfunction. Of the vasodilators mono-ethanol-amine-nicotinic acid appears to be the most effective in giving symptomatic relief. It has been found, however, that it is possible to achieve a considerably higher percentage of good therapeutic results if the intermittent vertiginous attacks are not associated with hearing loss but are of the type once characterized by Lindsay as "pseudo-Meniere's" disease.

Brunner reported that as a result of "vasomotor labyrinthitis" a hydrolabyrinth could be produced in which scala tympani and scala vestibuli showed equal or greater fluid accumulation than did scala media. He found that this condition might or might not result in the combined symptoms of pressure, tinnitus, deafness and vertigo. He was at a loss for an explanation of the variability of the symptoms.

Treatment

It is possible that this condition might be

related to failure of absorption of labyrinthine fluids and might be associated with cystic arachnoiditis of the cerebellopontine angle which some neurosurgeons have suggested to be a frequent cause of episodic vertigo with hearing loss. Drainage of the arachnoid sac has been reported to give long-term relief. It seems possible that the good results in "Meniere's syndrome" reported from the Portman-House procedure depend rather on relieving localized hypertension of cerebrospinal fluid rather than relieving hypertension of the endolymph.

Cogan's Syndrome

Manifestations

In a typical case of Cogan's syndrome the onset may be signaled by complaints referred to either the ears or the eyes. In some atypical examples of the condition, however, aural disorders predominate almost to the exclusion of eye symptoms.

It is interesting to note that the first case reported in the literature of a syndrome of non-syphilitic interstitial keratitis associated with vestibulo-auditory symptoms was reported as "Meniere's Disease Complicated by Recurring Interstitial Keratitis".

When Cogan identified this syndrome he included this case of Mogen and Baumgartner's as a typical example.

Cogan's syndrome is considered by most observers to be an instance of panvasculitis nodosa.

Many cases of Cogan's syndrome are difficult if not impossible to distinguish from "Rapidly Advancing Hearing Loss of the Younger Age Group" described by Sheehy. The hearing loss in both these conditions tends to be bilateral, with prolonged remissions, and further attacks are ushered in with a vertiginous episode.

It seems quite possible that Sheehy's syndrome and Cogan's syndrome may be closely related.

Treatment

In Cogan's syndrome glucocorticoid preparations are given in full dosage until a remission of symptoms had been obtained, and then cautiously reduced to a mainte-

nance dose, which must be continued for several months. This seems to give good results. The effect of this chemical in Sheehy's syndrome has not been reported.

Meniere's Disease

True Meniere's disease if selected according to the criteria suggested by the panel on vertigo of the National Institute of Neurologic Diseases and Blindness is a relatively rare condition not often seen even in a large outpatient service.

Manifestations

Since the hypotheses that Meniere's disease is caused by vasospasm, is untenable, as indicated by Davis. It has been suggested that the increased endolymphatic pressure is produced by the induction of histidine decarboxylase in a quantity far in excess of local homeostatic need, in a predisposed labyrinth, by stimuli arising from an ictal type of cellular "storm" in the hypothalamus. This would result in dilation of all vessels of the capillary beds of stria vascularis or the vas sperale below the basilar membrane with the secretion of an increased volume of endolymph.

Treatment

This hypothesis is supported by the fact

that eriodictyol glycoside in the form of lemon bioflavonoid complex has been found to suppress the symptoms of this condition.

Eriodictyol glycoside is one of the two bioflavonoids that Szent Györgyi found to have biologic activity.

Martin, Graff, Brendel and Beiler and Martin, Carley and Mok found eriodictyol and genesitin to be active in blocking histidine decarboxylase.

It is therefore considered probable that eriodictyol glycoside acts in Meniere's disease by blocking the activity of histidine decarboxylase.

Summary and Conclusion

Treatment of the episodic vertigos is not apt to be often successful if a single standard therapeutic program is applied to them under some meaningless cognomen such as "Meniere's syndrome."

It must be realized that intermittent stimulation of the labyrinthine system may result from a variety of causes. An etiologic diagnosis should be attempted. If this proves impossible, differentiation on the basis of the effect of treatment should be tried.

Post Hoc, Ergo Propter Hoc

The treatment of typhoid fever throughout the years has been variable and very interesting. An outstanding product used for a long period was antimony, which has no value in the treatment of the disease, but because it was given to Louis XIV and he seemed to improve following its administration, it became a favorite for years. Louis had been very ill with typhoid for a long time and showed no improvement with the usual concoctions of gold leaf suspended in wine, pearls dissolved in vinegar, and frequent poulticing. He was purged and bled, bled and purged and at last in desperation, his physician tried antimony. Louis was due to either die or get well and because the latter was in order, the antimony was given the credit.*

Rosemary

Rosemary is a plant of great service in affections of the head and nerves, helping the apoplexy, palsy, and all kinds of convulsions, pains and dizziness of the head. It strengthens the sight and memory.

— Dr. James

Postural Vertigo

JOHN R. LINDSAY, M.D.*
Chicago, Illinois

DISORDERS OF THE vestibular system characterized by vertigo of the postural type have been recognized for nearly half a century, but in recent decades the clinical significance and the pathophysiologic basis for their occurrence have been the subject for considerable investigation.

Definition

Postural vertigo refers to vertigo which comes on only during certain postures. It may come on abruptly during a change into a certain posture, or it may have latency, appearing some seconds after the new posture has been reached.

Positional Nystagmus

The most useful objective indicator and confirming sign of the vestibular disturbance is the accompanying positional nystagmus. Since Bárány's first description of positional nystagmus in 1921,¹ considerable progress has been made in its clinical recognition, the method of testing, and the appraisal of its significance.

Localization of the point of origin within the vestibular system is, however, often indefinite, and the neural mechanisms involved in the release of the nystagmus have in most instances remained obscure.

History

The patient who complains of vertigo seldom volunteers the information that distinguishes "postural" from other types. A few well-directed questions will usually bring out the postural nature of the symptom and so permit the examiner to differentiate at least three common types of vestibular vertigo. These are: episodic vertigo with rapid onset and recovery such as in Meniere's disease, continuous prolonged vertigo following an acute onset such as a

*Thomas D. Jones Professor of Surgery and Retired Head of the Section of Otolaryngology of the University of Chicago.

vascular lesion, and postural vertigo with or without a preceding acute onset of continuous vertigo. The patient with true postural vertigo usually gives a precise description of his symptoms in answer to a few selected questions. As in all cases of vertigo or disequilibrium, a general medical history is essential in the search for the cause of the disturbance.

Postural Tests

In addition to the routine ear, nose and throat examination the otoneurological investigation in all cases of vertigo should include routine postural tests. This should follow the tests for auditory function, disequilibrium, cerebellar function and spontaneous nystagmus, and it should precede the tests for vestibular function. Electro-nystagmographic recording of eye movements is useful in that it permits recording with the eyes closed and provides a record for later review. However, direct observation with the naked eye or with +20 diopter lenses or Frenzel's glasses to reduce fixation is adequate for clinical purposes.

Techniques

Two routines are in common use for changing postures. The simplest method consists of holding the patient's head slightly to the side between the examiner's hands and lowering it rapidly from the sitting to the supine position with neck extended. This is repeated with the head turned to the opposite side.

The more definitive method consists of using an orthopedic collar to prevent twisting of the neck, thereby preventing neck reflexes or alteration in vertebral vascular supply. Starting from the sitting position the routine may include supine, left lateral; supine, right lateral; supine, left sitting, then supine with collar removed and neck extended and rotated to each side in turn. Vertigo and nystagmus may occur during the change or may have a latent period; hence, 15 to 20 seconds are allowed before turning to a new position.

The test for positional nystagmus may in some instances depend on the rate at which

the posture is changed. Also the symptom may not be reproducible at the same examination.

Classification

Different classifications of the positional nystagmus have been used, mainly as an effort to evaluate its significance as to localization and etiology. The most commonly used is that which distinguishes three types based on its direction and duration.² One type is that in which the direction changes with the position or posture and is persistent. The second type is similar but the direction is always the same; while the third type includes a variety of transitory types, with or without latency.

Interpretation

The origin of the postural vertigo is best indicated by the associated findings, such as its association with a known inner-ear or retro-cochlear lesion or with indications of a central nervous system disturbance. Clinical observation has shown that the persistent types of positional nystagmus with or without vertigo are most suggestive of a central nervous system origin, whereas the transitory types may be of either peripheral or central origin.

Postural vertigo frequently follows an acute stage caused by partial lesions of the peripheral system³ such as viral labyrinthitis, vascular lesion with or without deafness, trauma during stapes surgery, ultrasonic therapy, and at times after an acute vertiginous attack in Meniere's disease. It also may occur in central nervous system lesions, including multiple sclerosis, tumor, vascular lesions and abscess. It is common following head injury, although localization may be obscure.

The transitory types are most common and their etiology often indefinite. They are frequently classed as "benign" since the vertigo is usually self-limited.

The term "benign" is questioned by some observers, since the "benign paroxysmal" type has been observed in cases of tumor of the posterior vermis⁴ and has been produced experimentally by cerebellar lesions includ-

ing the nodulus.⁵

Positional nystagmus has been produced experimentally by a variety of lesions of the peripheral vestibular system, including cutting the nerve to the utricle or to a semicircular canal.

Clinical Significance

Reliable evidence for a postural type of vertigo can usually be obtained by suitably chosen questions to the patient. Objective confirmation of its vestibular origin and organic nature can be obtained by observation of the positional nystagmus on postural

tests.

The presence of confirmed postural vertigo may be an early indication of progressive disease either of the peripheral or of the central nervous system; hence it is an indication for a complete otoneurological and medical evaluation.

Failure to recognize the postural character of the vertigo and to take steps to confirm its organic nature may result in dismissal of the complaint as purely psychogenic, or in overlooking an early sign of progressive disease.

Audio-Analgesia

Music to ease pain has been used for some time without any great scientific concentration on its possibilities. Today, a greater amount of attention is being focused on this particular area. Experiments are currently under way in which music and special static sound effects, known as "white sound", are played to a patient during certain types of dental or minor surgery. Preliminary results indicate that these combinations of relaxing music and somewhat disturbing white sound crowd the thalamus and cerebral cortex with a high level of sensory input and seem to reduce the sensation and recognition of pain.

— Bernard Seeman: Man Against Pain

|| Chemotherapy

in the Treatment of Head and Neck Cancer

JOHN F. DALY, M.D.*
New York, New York

THE GREAT SEARCH for effective chemotherapy against cancer has been going on for the past ten years. Efforts have been directed at discovering new antitumor agents and in developing methods of administering them. It seems appropriate at this time to review the contributions of chemotherapy to the management of head and neck cancer.

Oncolytic Agents

Of the thousand possible oncolytic agents that have been investigated only a few have reached the stage of clinical trial, and a still smaller group have proved to be of clinical value. These are:

Alkylating Agents-

1. Nitrogen mustard (HN2, Mustargen)
2. TSPA or Thio-TEPA (Triethylene thiophosphoramidate)
3. PAM (phenylalanine mustard, Melphalan)
4. Cyclophosphamide, AB-100, TEM

Antibiotics-

1. Actinomycin D
2. Mitomycin C
3. Streptonigrin, dihydro E-73

Antimetabolites-

1. MTX (methotrexate)
2. 5-FU (5-fluorouracil)
3. FUDR (5-fluoro-2-deoxyuridine)
4. 8-azoguanine

Experience

The selection of an agent should ideally be based on the tumor's response to the agent when administered systemically. However, there is no way of determining this interaction, except by experience. The use of tissue culture has not proved to be of practical value in testing the effect of an agent on the specific tumor cells. Therefore, the choice of an agent is usually determined by the

*Professor and Chairman, Department of Otolaryngology, New York University Medical School.

method of administration, as well as by the nature of the agent and the tumor response, as discovered by previous experience. Thus in perfusion techniques the short-acting alkylating agents are used, since the time of the perfusion is limited to one hour and the agent must destroy the tumor cells within that time. The treatment of melanomas of the head and neck is an example of the correct combination of administration and agent. Phenylalanine mustard, Melphalan, has been used most often in regional perfusion in melanomas of the head and neck. Nitrogen mustard, Triethylene thiophosphor and combinations of Triethylene thiophosphoramidate and phenylalanine mustard have also been employed and have been successful in producing total regression of the melanomas of the head and neck region. The alkylating agents have likewise been used successfully in the management of sarcomas. Favorable results have also been obtained with antitumor antibiotics given systemically. Embryonal rhabdomyosarcoma has been successfully controlled for a long period of time with a combination of agents, e.g., alkylating agents, antitumor agents and antimetabolites.

On the other hand, when antimetabolites are used, the exposure of the agent to the tumor must be continued over a longer period of time; for this reason continuous arterial infusion is the method employed. The two agents most commonly used are methotrexate and 5-fluorouracil. These agents have been most effective in the treatment of epidermoid carcinoma.

One should also mention hydrogen peroxide, which has been used by regional arterial infusion prior to and during radiation treatments. It is not an antitumor agent, however. This form of therapy is based on the enhancing effect of high oxygen content in the tissues during radiation. Objective evidence of this effect has been demonstrated in the reports of Mallams¹ and also of Corgill;² however, evidence that its long-term results are superior to radiation alone is still lacking.

The Administration of Antitumor Agents

Regional administration of agents is based

on the premise that the higher concentration of the agent in the tumor capillary bed will destroy tumor cells more effectively locally, while their dilution in the general circulation will spare the bone marrow and other vulnerable tissues. The two methods used are (1) regional arterial perfusion and (2) continuous regional infusion.

Regional Arterial Perfusion

In 1950 Klopp³ reported the use of nitrogen mustard by arterial perfusion in fractionated dosage in the treatment of cancer of the head and neck. Catheters were inserted into the external carotid artery. Bierman⁴ in 1951 reported the use of perfusion of nitrogen mustard, HN2, in the treatment of abdominal tumors. However, it was not until Creech⁵ in 1958 reported his results that regional perfusion began to be used extensively in the treatment of cancer. The rationale of this technique is to bring a high concentration of the oncolytic agent to the tumor bed while protecting the other vulnerable organs by isolation of the anatomic region from the general circulation. The agent is delivered into the arterial blood supply and picked up in the venous return, so that very little leaks into the general circulation. In the head and neck region the rich anastomosis makes complete isolation impossible, a serious limiting factor to the employment of perfusion techniques in the head and neck. The other factor is the narrow therapeutic index of alkylating agents, which are also toxic to normal tissues in the therapeutic concentrations used. A most serious complication of perfusion of the head and neck region is leakage of the alkylating agents into the internal carotid and the subsequent marked brain reaction and edema.

Creech⁵ used an extracorporeal pump and oxygenator. The trend has been toward simplification by elimination of the oxygenator and the use of a hand pump. Golomb⁶ has used this system as an adjunct to surgery. The tumor bearing area is perfused prior to its removal at the time of surgery. Harrison⁷ has also employed perfusion at the time of surgery, followed by radical excision of the tumor bearing area.

Regional Arterial Infusion

Sullivan and his colleagues⁸ in 1959 reported on the use of continuous arterial infusion for the treatment of tumors. Polyethylene catheters were inserted into the external carotid arteries for the treatment of malignancies of the head and neck. The anti-tumor agent methotrexate (MTX) is delivered continuously in high dosage (50 mg/24 hours) over a long period of time, usually ten days. No attempt is made to prevent the agent from entering into the general circulation. Protection of other vulnerable organs is accomplished by intramuscular injection of citrovorum factor (6 to 9 mg. every four to six hours).

The rationale of this method is based on three factors: (1) that cells are vulnerable to the antimetabolites only during the active phase of cell division, (2) that populations of tumor cells go into cell division stage at different times, and (3) that by infusion the antimetabolites are constantly present in the tumor bed in high concentration.

Methotrexate (MTX) has been most widely used following the technique of Sullivan.⁹ Johnson, Kiskin and Curreri¹⁰ have used 5-fluorouracil by continuous arterial infusion in a variety of tumors and followed this in three to four weeks either with surgery or radiation therapy whenever possible. As with most reports on chemotherapy both groups of investigators find that the number of immediate responses is encouraging, as are the preliminary recurrence and survival data in a group of patients with far advanced carcinomas of the oral cavity and pharynx.

Infusion remains the principal method of administering antitumor drugs in the treatment of head and neck malignancies. Many technical improvements have been added, including the insertion of catheters through the superficial temporal artery, improvements in the catheters themselves, and the simplification of the pump. The improvements help to solve the technical difficulties and reduce complications but do not alter the overall response of the tumor to the agent.

At the same time the procedure of perfusion has become more complicated. Boy-

land¹¹ has shown that nitrogen mustard is less toxic to the whole body when systemic hyperthermia is maintained during its administration. Shingleton¹² has also demonstrated that bone marrow is protected during hypothermia. Harrison⁷ has added hypothermia to his regimen. He pointedly remarks that perfusion with hypothermia for the body and hyperthermia for the regional perfusion has now become so complicated that it should be carried out only in a center for chemotherapy with a trained staff and with special facilities for the management of the patient and the complications. This is very sound advice for any form of chemotherapy.

Complications

There are several factors which limit the general use of tumor chemotherapy. These include the local and systemic effects on normal tissues, the technical difficulties of inserting catheters into the arterial system and maintaining their function, and the complications which arise from these procedures. The latter include hemorrhage, sepsis, vascular spasm, necrotizing arteritis, emboli formation, and thrombosis of the vessels. Transient and permanent hemiplegia is not an uncommon sequela. Reports of transient hemiplegia vary from 8 to 30%.

Combined Chemotherapy Regimens

Chemotherapy rarely produces a cure even when total regression of the tumor takes place. Biopsy specimens from the tumor site have viable tumor cells present. For this reason chemotherapy is now frequently used as an adjunct to surgery or radiation. Thus, perfusion of the isolated or semi-isolated tumor bearing area with an alkylating agent at the time of surgery has been employed by several surgeons. Harrison⁷ widely removes the perfused tumor tissue immediately after perfusion in order to forestall necrosis, sepsis and hemorrhage which might follow the destruction of the tumor. Johnson et al.¹⁰ have resected the tumor area three to four weeks after successful regression of the tumor or have used radiation therapy at this time.

Because of the complications arising from arterial infusion of the tumor site, Daly and Friedman¹³ have employed methotrexate (MTX) 7.5 mg. daily by mouth for ten days, in combination with radiation therapy. Their results are similar to those obtained by continuous infusion. Ten percent of the patients showed complete to near complete regression of the tumor on oral MTX prior to the start of radiation; two thirds showed fifty percent shrinkage, and fifteen percent showed no response. Radiation was added to the course of methotrexate. Oral methotrexate appeared to enhance the effect of radiation on the tumor. The authors express their enthusiasm for the encouraging results, but admit that a controlled study is needed to prove enhancement.

Results

Since antitumor chemotherapy rarely if ever produces a cure, its principal value lies in its ability to control the disease by producing a temporary regression of the tumor and an amelioration of symptoms. Reports in the literature are enthusiastic and hopeful but lack objective criteria for judging the over-all effect of the therapy on the course of the disease. Its palliative effects are real but temporary, recurrence within three months or less being the general rule. For this reason most investigators are combining chemotherapy with the two well established modes of cancer therapy, namely, surgery and radiation. To establish statistically an enhancing effect on the cure rate of five to

ten percent presents a formidable task, requiring the cooperation of a large number of clinics. Prospects for this type of study do not seem to be feasible, although some are already courageously trying to organize a national study of combined chemotherapy and radiation.

Conclusion

Antitumor chemotherapy by regional arterial administration is capable of producing a temporary control of the disease as judged by gross regression of the tumor and palliation of symptoms. Reports indicate that chemotherapy may enhance the cure rate of surgery and radiation when used in combination, but we do not have a controlled study to prove it. Local and systemic toxic effects and the complications from the arterial method of administration are factors which limit its general use. Oral methotrexate in combination with radiation therapy will produce a regression of the tumor, may enhance the cure rate in far advanced disease and is worthy of a trial. However, all precautions should be followed to avoid the systemic toxic effects of these lethal agents. Finally, the seriousness of the complications arising from the use of chemotherapy, plus the fact that chemotherapy is still in an experimental and developmental stage, makes it desirable to establish a tumor chemotherapy unit within a hospital complex where special equipment and personnel familiar with its problems may function to the benefit of the patient.

The soul's maladies have their relapses like the body's. What we take for a cure is often just a momentary rally or a new form of the disease. — La Rochefoucauld

Intranasal Medication

O. E. VAN ALYEA, M.D.*
Chicago, Illinois

MEDICAMENTS, FOR a number of years, have been packed, sprayed and instilled into the nasal cavities by physicians in their treatment of various ailments of the nose and sinuses. Throughout most of this time, their efforts have been directed largely toward alleviating symptoms, rather than toward eliminating the conditions or disease causing the symptoms. Intranasal medications have been used in the management of the common cold, acute nasal and sinus infections, vasomotor disturbances, acute and perennial allergy upsets, longstanding head colds, atrophic rhinitis, chronic sinusitis, and various aches and pains about the head and face. It is, however, the opinion of most rhinologists that, with slight exception, little is to be gained by the use of most of the methods of intranasal medication.

Historical Items

In the early days, prominently displayed in most physicians' offices, was an array of spray bottles, containing oily solutions of different colors and aromas. The patient inhaled these, either in rotation or in accordance with the physician's mood and, as far as is known, no benefit was ever derived from their use.

Some time later the spray bottles were replaced by tamponage therapy with argyrol packs** which were inserted into the nose for twenty to thirty minutes. This was often repeated daily.

These packs in the nose are harmful in the acute stages and of no curative value in the chronic stage. In subacute infections, their irritating action produces a flow of mucus which some think of value. The same effect, however, can be attained by a few whiffs of snuff and with less damage to the nasal mucosa. The principal objection to the use of argyrol packs is that physicians,

*Department of Otolaryngology, University of Illinois, College of Medicine.

**Dowling packs.

who commonly use this method apply it to all patients with nasal complaints regardless of the nature of the ailment, are prone to develop loose diagnostic habits.

Shrinking nose drops came along a few years after Chen introduced ephedrine to occidental medicine in 1926. Ephedrine is an alkaloid derived from Ma Huang, known to the Chinese for many years as an anti-asthmatic and diaphoretic. The physiologic effects of ephedrine are principally due to its stimulating action on the sympathetic nerve endings in the nasal mucosa which produces nasal vasoconstriction.

Decongestant nose drops were welcomed by rhinologists and represented a period of enlightenment founded on what Proetz called the "rediscovery of the cilia."¹⁻⁵

Research initiated then and during the ensuing years aroused an interest not only in the ciliated mucosa but in all phases of nasal physiology with the result that much of the confusion previously existing in rhinology has been dispelled.

We know now that the membranes which line the nasal and sinus cavities are ciliated and covered with a thin layer of mucus in which the cilia beat. The mucociliary mechanism with its sticky surface guards against invasion of the tissues by pathogenic organisms, which are conveyed to the nasopharynx promptly; and only in the event of a breakdown in the mucociliary stream do the pathogens gain a foothold in nasal membranes.

By far the most common means of disrupting this defense mechanism is body chilling. This produces intranasal vasoconstriction, with lowered temperature and a blanching of the membranes which cover the intranasal structures. As the circulation is diminished, there is a cessation of glandular activity; the nose becomes dry and the cilia cease to beat.

A return of intranasal function will occur with the application of heat, either locally or to the periphery; or, if the individual's resistance is good, a compensatory action re-establishes nasal function in ten to twenty minutes in spite of continued exposure to cold.

Acute Nasal Infection (Common Cold)

It is a generally accepted belief at the present time that the micro-organisms usually associated with diseases of the upper respiratory tract have nothing whatever to do with the onset of the attack. They are secondary invaders only, coming on after the way has been paved by some other influence.

The early invader is thought to be a filterable virus which confines its activities to the initial stages of the disease.⁶

Just what part the virus plays in the onset of a cold is purely conjectural. Some investigators think the viruses pass through the ducts of the goblet cells and mucous glands; others think that in order to be available at the proper time the viruses must reside in the nasal mucosa of cold-susceptible individuals. The goal of many of the virologists at the present time is the development of a vaccine capable of establishing an immunity in human individuals. It is thought that success in this project is contingent upon development of a vaccine against a sufficient number of the specific viruses now known to exist.

General Management

Bed Rest and Moist Air

All writers agree that patients with acute rhino-sinusitis do better when put to bed in a warm, well-moistened room, and that simple common-sense treatment hastens recovery and prevents complications. Energetic local treatment is avoided, but measures to increase the comfort of the patient are introduced early and maintained throughout the course of the disease.

Local Heat

Important to the patient is the application of heat to the face. This may be in the form of hot moist towels or infra-red rays and are especially welcome during the engorged state of the nasal membranes.

Nasal Pack

For those complaining of excessive con-

gestion and pain, a soothing nasal pack also is indicated. This consists of cotton saturated with equal parts of ephedrine (0.5 per cent) and pontocaine hydrochloride (0.5 per cent). This is gently inserted into the nose in the area of the middle meatus and left in place for thirty minutes while the patient is also receiving external heat. With the removal of the packs the pain and congestion disappear, and this relief may remain for hours.

The shrinking effect of ephedrine on the swollen nasal membranes of an acute head cold affords immeasurable relief, yet its excessive use is discouraged, for its benefits must be weighed against the detrimental effects of the application which removes protective hyperemia of the nasal tissues, lowers local resistance and violates the principles of acute inflammations.

To be deplored is that practice of many physicians today who prescribe shrinking nose drops for the complaint of impaired nasal breathing without first seeking the cause and nature of the blockage. Even though a diagnosis has been reached, vasoconstrictors should be prescribed only with the understanding that very little of a curative nature may be credited to them and that the relief afforded will be temporary only. It should also be kept in mind that the continued use of nasal vasoconstrictors may lead to disturbances of nasal function to such an extent that allergic conditions remain neglected or uncontrolled and pathologic membranes may progress to a state of chronicity.

Rhinitis Medicamentosa

This title has been applied to the condition of the nasal mucous membranes which results from overuse of shrinking solutions in the nose. The mucosa covering the intranasal structures becomes pale and edematous. The swelling is sufficient to block the nasal airways and the condition persists except when a temporary respite is gained by a further application of a nasal decongestant. This form of rhinitis may be produced by the continued application of almost any of the vasoconstrictors in common use but

has especially been noted following the use of privity hydrochloride, a drug recognized for its prompt, pressor action.

Illustrative Case

A pronounced case seen by the writer a few years ago is typical of those cases occasionally encountered by all rhinologists.

Figure
Head in low positions for intranasal medication and displacement (suction) therapy. (Top) The Proetz position. (Bottom) The side position of Parkinson.*

*Postgraduate Medicine, November, 1963, p. 474.

Mr. D. had been using privity steadily, for three years as often as every two hours, day and night. Examination revealed pale, boggy nasal mucous membranes which completely blocked both nares. Pus was observed in the middle meati and irrigation brought a return of considerable pale exudate from both antra. He immediately stopped the use of all nose drops; but to aid him in sleeping with a blocked nose he was given phenobarbital each night for five nights and reported that on the sixth day his nose opened up satisfactorily. He was given dust extract injections in a dilution of 1 to 100,000 each week, and at the time of the injections the sinuses were irrigated. The sinuses were negative on the sixth irrigation and have remained so since then; now he no longer has the complaint of nasal stuffiness.

Nose drops employed in office practice are indispensable. As a shrinking agent to permit better visualization of intranasal structures or as a vehicle in displacement therapy, they occupy a highly important position in the rhinologist's office.

If nose drops must be prescribed for home use, only those which meet certain requirements should be considered. They should as nearly as possible simulate the normal secretions of the nose. They should be isotonic and non-detrimental to ciliary activity; they should also be non-irritating with a pH slightly on the acid side, and they should not be of the type which leads to a dependency on their use. Ephedrine 0.5 per cent in normal saline solution and many of the synthetic sympathomimetic preparations now available fulfill the requirements.

Instillation in a head-low posture is perhaps the most effective method of applying intranasal medication. The patient is placed on his back on a treatment table or bed, with his head extended so that it hangs over the edge of the table. The Proetz position calls for an extension sufficient to place the chin and the ear in the same vertical plane. In the Parkinson side-posture position, the patient is on the side with his head hanging over the edge.

The latter position is used with older people, those with thick necks, and those who complain of a feeling of flightiness or dizziness when the head is hyperextended.

Displacement Therapy

During the forty years since its origin,

the Proetz technic of introducing fluids into the sinuses has gained considerable vogue both in this country and abroad. This method is not advocated for use in the treatment of an acute cold or in the presence of an elevated temperature. It is, however, regarded as our one effective non-surgical means of dealing with chronic ethmoiditis or low-grade long-standing nasal infections.

Technic

The patient is placed on a table in the Proetz position while decongestants are instilled into the nose. After 30 to 60 seconds the nasal cavities are filled with warm, normal saline solution. Displacement is produced by alternative suction with release of suction a few times. If mucopus is withdrawn or blown out later, a positive diagnosis of ethmoiditis may be made.

Summary

Throughout the years, medicaments have been packed, sprayed and instilled into the nasal cavities by physicians in their treatment of various ailments of the nose and sinuses. It is, however, a known fact that little is to be gained by use of most of the methods of intranasal medication so far devised. Unfortunately, during the early decades of rhinology, little was known of the function of the intranasal structures that were being treated, and it was not until the mid 20's that much interest was displayed by rhinologists in nasal physiology and histopathology.

Intranasal medication at the present time is dependent largely on decongestant nose drops, which are not a great improvement over the medications of the past.

The shrinking effect of ephedrine and many of the other synthetic sympathomimetic preparations on the swollen nasal membranes of an acute head cold affords immeasurable relief, yet excessive use is discouraged, for the benefits must be weighed against the detrimental effects of the application which removes protective hyperemia of the nasal tissues, lowers local resistance and violates the principles of acute inflammations. It would seem then that the ideal nose drop

has not yet been discovered and that its discovery will have to be delayed until we learn more about the conditions which cause swelling of the nasal mucosa. A great step was made in this direction when it was deter-

mined that most of the stuffy noses for which sub-mucous resection was carried out received no improvement in their blockage until their nasal allergy also was brought under control.

President's Letter
(Continued from page 807)

coming in from all over the state.

I would suggest that a private, separate facility be built close by the Medical School, housing the offices of a number of family physicians, also interested in teaching, who could be made part or preferably full-time faculty members, but who would use the various departments within the University Hospital for their referrals, wherever possible for and agreeable to their patient-clientele. In this way all students could spend part of their time working in this private-practice setup, seeing many of the routine cases that come into the average family physician's office, which they would never otherwise get exposed to on their way through school.

Thus, by both precept and exposure more students might decide that they would prefer this type of practice, and thus begin to resolve the shortage problem. Admittedly this would take time; but it might pay off in the long haul. Their patients would be almost entirely private patients; the so-called charity or welfare patient is going to become an ever-diminishing quantity with "Uncle" footing the bill in ever larger numbers.

Let these thoughts of mine hopefully add something constructive to the other ideas which will be generated over the next few years for solving the very vexing problems of medical care and teaching with which we are now critically faced.

I am delighted to have the opportunity to pay my own tribute, as well as that of the entire Minnesota State Medical Association membership, to a man who has been a tremendous teacher and friend of so many of us who have been graduated from the University of Minnesota. Dr. Larry Boies succeeded one department head whose shoes were very large indeed, Dr. Horace Newhart, nationally recognized as one of the top men in his field. Dr. Boies has completely measured up to Dr. Newhart's image, in the opinion of those who know him best, and this is the greatest accolade I can give him. This issue is devoted to Larry's specialty, ENT, and it could not happen to a finer man.

C. G. Sheppard, M.D.
President
Minnesota State Medical Association

Formula for a Soporific Sponge

Take of opium, juice of hyoscyamine, unripened berry of the blackberry, lettuce seed, juice of hemlock, mandrake, ivy . . . put these all together into a vessel and plunge therein a new sea sponge just as it comes from the sea, taking care that fresh water does not touch it. Then put this sponge in the sun during the dog days until all the liquid is evaporated. And when there is need, dip it a little in water not too warm, apply it to the nostrils of the patient and he will quickly go to sleep. When you want to awaken him, apply juice from the root of the fennel and he will soon bestir himself.

Nicholas of Salerno: Antidotarium (12th century)

Aural Symptoms of Psychosomatic Origin

GORDON D. HOOPLE, M.D.*
Syracuse, New York

THE EXACT SEQUENCE of physical changes which takes place as a result of a psychosomatic disturbance has been the subject of considerable debate. Vasospasm as a result of tension is the most frequently mentioned cause. However, fear, anxiety, frustration, guilt and sorrow appear to create the same physiological change.

Various parts of the body such as the brain, the heart, the stomach, the intestines, the skin, the eyes and the ears may be the shock organs which give rise to upsetting symptoms. While the stomach appears to be the organ most frequently involved, the ears are not far behind.

Psychosomatic Turmoils

There are four main symptoms pertaining to the ear which may be due to psychosomatic turmoils. These are itching of or in the ear, tinnitus, loss of hearing, and dizziness. There are other symptoms, of course, but these four occur with the greatest frequency. To state that the four are always psychosomatic in origin would be erroneous, for each in turn may also have an organic etiology. As a matter of fact the etiology of any of the symptoms mentioned may be both organic and psychosomatic. It is sometimes difficult to assay which is the more important component.

Itching

Itching of the ears will be discussed first because in reality it is not an ear symptom. It is only one location where skin reactions may be manifest. However, for the person involved it can be a very annoying symptom. The very best management is to leave the itch in isolation, not to scratch it. Few victims resist the temptation to do so. The usual result is an aggravation of the original symptoms and this often results in complications which can be more annoying than

*Professor Emeritus, Department of Otolaryngology, State University of New York Upstate Medical College.

the original condition. Scratching often introduces infection and if infection is present scratching can be vigorous enough to cause an abrasion of the skin. When a break of the skin occurs in the presence of infection, very painful furuncles or abscesses of the ear canal can follow. The best management of itching of the ear, then, is to ignore it — which can be done with the use of sufficient will power. The physician consulted should remember that the itching is only a manifestation of a disturbance of the skin and he should direct his attention to putting this portion of the body in the best possible condition. He should give some thought to discovering a possible psychic cause. It is often present.

Tinnitus

Probably everyone throughout all history, at one time or another, has been the subject of the sensation of tinnitus. But with the vast majority this has been momentary and very infrequent. The cause of these only seconds-long experiences is debatable, but it is probably vascular in nature. Their significance is negligible. When tinnitus is constantly present (heard for hours on end) it is another matter. This form of tinnitus usually represents some deterioration of the nerve of hearing or of its central connections. The tinnitus can take many forms. It can be a ringing, a roaring, a buzzing, a whistling, and be high pitched or low pitched. It can be steady or pulsating. If it is pulsating in character its cause is most likely to be a gross vascular lesion, i.e., arteriosclerosis or an arteriovenous aneurysm. If so, it is organic in origin and is not a matter of concern for this paper. The origin of tinnitus can be strictly organic, caused by any agent which would bring about a loss of function of the nerve of hearing. Human beings are exposed to many such agents. Life is full of such expectancies. It is surprising that *all* adults do not have tinnitus. If physical causative factors are so abundant, what part does the psyche play in the origin of tinnitus?

It is possible that the cause of tinnitus can be entirely psychogenic. The ears and

the eyes are the most sensitive organs of the body. Any disturbance of the vascular supply to the ears can result in temporary derangement of the function of the nerve of hearing. If the disturbance is temporary the resulting tinnitus may be fleeting in character. An occasional psychogenic disturbance thus may result in little or no tinnitus. A prolonged or a severe emotional experience may be the cause of a lengthy or even a permanent tinnitus. If the ear happens to be the individual's most sensitive shock organ tinnitus is more apt to ensue.

Tinnitus can be tolerated. This is the most important message a physician can give to his patient. Almost every victim of tinnitus has had the thought that his tinnitus is a symptom of a brain tumor. When the character and import of this symptom is explained, the patient is vastly relieved. Tinnitus is always worse when the patient is tired or nervous. Thus it can be a signal to which attention should be paid so that rest should be taken or a change in thinking should be made.

The sensation of tinnitus is controllable. The author has a constant tinnitus, yet for better than 99% of his waking hours he never "hears" it. At the moment of this writing it is ringing full blast. His attention has been called to it. The psyche then can be used to "cure" tinnitus. Here the psyche can play one of its most important roles in aural symptoms of psychosomatic origin.

Hearing Loss

Most hearing losses are caused by organic etiologies. But the same mechanism which is at work in creating tinnitus can cause a hearing loss. Perfectionists and "worry warts" are more susceptible than calm, care-free individuals. It is not often that a severe bilateral hearing loss can be attributed to psychosomatic causes, but occasionally this is true. However, a severe bilateral loss can occur, particularly if the individual is a highly susceptible person, as shown by lesions (from the same cause) in his heart and stomach or in other shock organs. If a patient has had a stomach ulcer for years and has had one or two coronary episodes,

and if a hearing loss exists, it is likely that the loss is psychogenic. Fortunately many of the hearing losses which can be attributed to psychogenesis are moderate in degree. Occasionally there is a severe unilateral loss which may be due to emotional disturbances.

The psyche plays another role in hearing losses. This is when there is a psychogenic loss as an overlay on a true organic loss. Mostly this is found in patients who subconsciously wish to "use" their hearing loss to their own advantage. The hearing loss is not as great as it is pretended (consciously or unconsciously) to be. To separate one from the other and prove that in reality the overlay does exist takes a large measure of diagnostic skill.

Finally, there is the psychogenic loss which is present when a patient has normal hearing. In large measure this is created when an escape from reality is desired or when it is "needed" as an attention getter. The attention-getting motive is more often found in children, the escape motive in adults, though the motive for the "loss" may be just the opposite. Most adults have the "loss" because they do not want to hear. Children have it to get the love and attention which they crave and are not getting. The cure for such losses is psychological or psychiatric.

Dizziness

Dizziness arises from involvement of the ear in a different location than when hearing is altered. It arises from disturbances in the labyrinth rather than in the cochlea to which attention has been drawn to this moment. Dizziness is a sensation of motion when there is none. The complaint of dizziness is common and may vary from a slight sensation of imbalance to a whirling sensation which is so severe that the patient may hold on to the head of his bed because he does not wish to fall off.

There are two problems connected with dizziness to which a physician should be alert. The first is to determine if possible that dizziness truly exists. Light-headedness is not dizziness, yet it may be difficult to ascertain which one of the two is present. **The differentiation must be made chiefly by**

careful history taking. There are few occasions in medicine that cry out for more careful probing. Some patients cannot describe their sensations accurately. This puts a double onus on their doctor.

The second problem is to determine, if possible, whether the dizziness is due to a peripheral origin (the ear) or a central origin (the central nervous system). The solution of this problem lies more in the realm of the physical examination than in history taking.

Psychic factors which cause dizziness more often affect the ear than the central nervous system. If a hearing loss in one or both ears is a concomitant symptom, it is probable (though not certain) that the organ giving rise to the dizziness is the ear.

There are several organic causes for involvement of the labyrinth. But psychic factors can and do affect this organ. They must, however, affect one labyrinth more than the other, for the two labyrinths must be out of balance if dizziness of the aural origin is present. Psychic factors do just that, affect one ear more than the other. It is a well known anatomical fact that no two sides of the body are exactly alike, and this is probably the reason why so often one ear is involved and not the other.

What we are saying is that vascular changes brought about by psychosomatic disturbances affect the labyrinth as well as the cochlea. Vascular changes are present at the time of the menopause. Add to this the psychic storms which menopause creates and you have good reason for the prevalence of dizziness in women at that time.

In the opinion of this author there are many more instances of dizziness due to psychic factors than there are due to organic causes. Seventy-five percent of labyrinthine tests performed on patients whose history or other physical examination suggests the necessity for caloric testing have a response to the test that is within normal limits. When both normal responses and dizziness are present in the same patient it may be assumed that there is no organic pathology in the labyrinth and that the dizziness is the result of abnormal physiology.

Altered physiology is the first stage in the course of psychic disturbances. Later irreversible pathology may come into the picture. This often happens. The time to nip dizziness in the bud, if it is psychogenic, is at its outset.

Conclusions

Story after story could be told of psycho-

somatic origins of aural symptoms. But this would unduly lengthen this presentation. Suffice it to say that they do exist and they can be the most exciting detective stories. The trouble is that too many doctors think they are too busy to solve these puzzles with which they are confronted.

Allergic Dysfunction

The Fundamentals

HARRY P. SCHENCK, M.D.*
Philadelphia, Pennsylvania

TO SOME EXTENT, recent investigations have clarified the role of the eosinophile in allergy by providing new information concerning other cells participating in tissue changes due to allergy.

Although Paul Ehrlich discovered basophilic tissue granulocytes in 1877, giving them the name of "mast cells" and reporting their increased number in chronic inflammation of connective tissue as well as the reciprocal relationship of mast cells and eosinophiles, 80 years elapsed before the recognition of the collagen diseases again focused the attention of investigators on the physiological and pathological significance of these biologically active cells.

Location of Allergic Pathology

The pathology in various allergic diseases, including hay fever, perennial nasal allergy and vasomotor rhinitis, is primarily in the ground substance of the connective tissue and consists of edema accompanied by an increase and liquefaction of the amorphous substance. Of the main cellular constituents of fibrous tissue, fibroblasts are concerned with the production of collagen fibers, whereas mast cells produce hyaluronic acid which has a regulating influence on ground substance, and also store histamine, heparin and many other substances which they liberate in the inflammatory chain reaction.

The Role of Mast Cells

Mast cells participate in the earliest phase of the local reaction of connective tissue to injury. They are the source of numerous substances, of which the most important are heparin, histamine and 5-hydroxytryptamine, and contain large granules which are dispersed extra-cellularly when they rupture or degranulate under the influence of many exogenous and endogenous substances. Various histamine liberators induce swelling, vacuolation and, finally, disruption of the mast

*Emeritus Professor, Otolaryngology, University of Pennsylvania.

cells with liberation of their contained granules. There is then an immediate release of histamine which produces vasodilation of the regional vessels, flooding of the injured zone with protein-rich lymph, and by direct action on the nearby connective tissue cells, increases their phagocytic activity and capacity. The connective tissue cells promptly ingest and digest the heparin-containing mast cell granules and are stimulated to produce mucopolysaccharide ground substance of their own.

Antigen-Antibody Reaction

It is probable that the antigen-antibody reaction underlying allergic reactions depends upon the exposure of plasma cells to the antigen followed by the manufacture and release of specific antibodies by the exposed cells. The specific antibodies, when released from plasma cells, become attached to accessible mast cells. When the specific antibodies produced by plasma cells reach such altered mast cells, a reaction takes place between the antigen and the antibodies attached to the mast cells, resulting in lysis of the mast cells and distribution of the granules of heparin or a heparin-like substance in the extracellular spaces.

The Plasma Cells

The role of the plasma cell in antibody formation is limited to the synthesis of gamma globulin which contains practically all of the humoral antibodies. While most antibodies are produced within lymph tissue where the cellular response is predominantly lymphocytic, lymphocytes do not manufacture antibodies although they play an important role by providing the energy and raw materials essential for the synthesis of antibodies by plasma cells during the course of lymphocyte degradation. The function of reticuloendothelial cells and leukocytes is probably limited to the splitting of aggregated or corpuscular antigen into chemically active antigenic molecules capable of stimulating the synthesis of antibodies by plasma cells.

The Circulating Cells

Mast cell lytic antibodies are not neces-

sarily specific to these bodies and they are also very active in causing damage to other cells. In localized allergic lesions, observed at an early stage, there is arteriolar contraction with obliteration of the lumina of the arterioles and temporary stoppage of the circulation due to action on the smooth muscles of the vessels. There is also an increased adherence of leukocytes to the blood vasculature endothelium, and emigration of leukocytes in large numbers through the walls of the capillaries and venules. The leukocytes within the capillaries stick to each other to form clumps, or emboli, which block the circulation in many of the capillaries and venules; but these manifestations are reversible and cease when the specific antibody is no longer available.

Normally in the upper respiratory tract, eosinophiles are distributed in the main in the middle submucosal layer and directly bordering on the epithelium and very rarely in the deep submucosal layer; mast cells are present almost exclusively in the deep submucosal layer. During active nasal allergy, degranulation of mast cells and release of histamine appear at an early stage and, if the reaction continues, there is a drastic numerical decrease which may continue until no identifiable cells of this type can be found even in the deep submucosal layer of the epithelium. Concomitantly with the mast cell decrease is an increase in eosinophiles which tend to occupy the entire submucosa. It is believed that the eosinophiles are attracted by the histamine present and proceed to alter or destroy it. Wherever edema is most marked, few or no mast cells are found, but eosinophiles are numerous. When the antigen-antibody reaction subsides, mast cells reappear and the number of eosinophiles diminishes.

Mast cells are sparse or absent in mucous nasal polyps although a few may remain in the deeper tissue near the attachment of the polyp. On the other hand, eosinophiles may be numerous at certain stages and are mostly concentrated in areas containing a greater histamine concentration. Plasma cells appear in large numbers in polyps containing polyp fluid with a high gamma globulin con-

tent but there is no correlation between the number of eosinophiles present and the increase of gamma globulins in the polyp fluid. Here, as elsewhere, wherever an appreciable quantity of histamine can be demonstrated, no undamaged mast cells are found as a result of their degranulation with the liberation of histamine.

Conclusions

A direct approach to the solution of the role of the eosinophile in allergy has been frustrating in the past, but the enigma appears to be much nearer solution with the recent dynamic extension of our knowledge concerning all of the cellular elements involved in allergy and anaphylaxis.

Gerlier's Syndrome

This syndrome is characterized by paroxysmal attacks of severe vertigo and muscular weakness. It was described by Felix Gerlier of Switzerland in 1887. Because this unusual condition occurs in limited areas geographically, little is known concerning it except the symptomatology. Sudden severe vertigo is usually the first symptom. Drooping of the eyelids partially obscures vision. There is pain in the nuchal and spinal muscles, followed by weakness of the cervical muscles with inability to hold the head erect. Severe vertigo and weakness of the limb and trunk muscles may make sitting or standing impossible. Attacks are episodic and may recur daily or more frequently, with varying degrees of severity in different persons.

Most of the reported cases of the syndrome have occurred in southern Switzerland and in Northern Japan almost invariably during the summer months. It most commonly occurs in healthy young farm workers, often in several members of a family. The etiology remains obscure. The degree of incapacitation may be mild or severe and prolonged for a few months. Treatment is symptomatic. In most cases complete recovery ensues after the onset of cold weather.

Medical Men on Postage Stamps

Charles Richet (1850-1935) was a French physiologist and Nobel Prize winner (1913) who did research work on the role of conditioned reflexes in digestion and discovered that gastric juice contains hydrochloric acid. In collaboration with *Paul Portier* he achieved distinction for his work on immunity and its converse, anaphylaxis, for which both men were honored by a postage stamp issued in Monaco in 1953.

Ignaz Semmelweis (1818-1865) was a Hungarian obstetrician, who as assistant in the obstetric ward of Vienna's general hospital reduced the mortality rate there from 9.92 to 3.8 by rigid standards of cleanliness. His discovery of the cause of puerperal fever was commemorated by Germany on a postage stamp issued in 1956.

PSYCHIATRY RESIDENCY POSITIONS AVAILABLE: July 1967 for three-year accredited program. A dynamically oriented broadly-based well-balanced opportunity for sound training. Meadowbrook Hospital is Nassau County General Hospital and is centrally located in the most desirable and beautiful area in the country. Easy commuting distance to New York City. 3000 inpatient psychiatric admissions per year. 24-hour walk-in clinic and all psychiatric modalities. J. Martin Semer, M.D., Chairman, Department of Psychiatry, Meadowbrook Hospital, P.O. Box 175, East Meadow, Long Island, New York 11554.

WANTED LOCUM TENENS: Three-man Minneapolis GP group desires physician with Minnesota license to work during July, 1967. Salary and conditions excellent. Contact: 529-9251, Minneapolis.

GENERAL PRACTITIONER wanted to join well established practitioner. Located 65 miles north of Minneapolis-St. Paul area. Population over 3,000. Hospital in town. Good schools, churches, and fine fishing and recreational area. Contact: A. C. Peterson, M.D., 200 E. Forest St., Mora, Minnesota 55051.

FOR RENT: Modern suburban office space now available, with large private parking area, on South Robert near Signal Hills. Successfully occupied by doctors for last twenty-five years. Newly remodeled. Reasonable Rent. 950 South Robert. Telephone: 224-7913, St. Paul.

GENERAL PRACTITIONER, associate wanted to join 34-year-old solo GP in a not excessively active family practice in a N.E. suburb of Minneapolis. Modern office with complete x-ray and lab facilities, 15 min. from a large hospital with affiliated nursing school and residency program all fully accredited, 20 minutes from the University of Minnesota and the downtown area. Gary Good, M.D., 3827 Central Avenue N.E., Minneapolis 55421. Write or call collect 613-788-9091.

WANTED: General surgeon to associate with six-man group. Progressive Northern Minnesota Junior College Town. Modern 150 bed hospital. Excellent hunting and fishing. Near metropolitan area. Contact: Falls-Starekow Clinic, Thief River Falls, Minnesota.

LOCUM TENENS wanted for general practice from now through summer 1967. Write: MINNESOTA MEDICINE — 377, 496 Lowry Medical Arts Building, St. Paul 55102.

WELL ESTABLISHED, unopposed general practice with clinic in prosperous community with large rural area in Minnesota. Have practiced general surgery and medicine in this community for over thirty years. Reason for selling: retiring. Willing to practice for few months to acquaint buyer with patients. Reference may be obtained regarding my reputation. Wonderful opportunity for two or three young doctors interested in surgery and general practice. Clinic may be financed by community if so desired. General hospital open and owned by local community. Clinic within area of Twin Cities. Write: MINNESOTA MEDICINE — 379, 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED — GP to take over practice due to health. Equipment and all available with good financing. N.W. Suburban Minneapolis. Call or write Allen G. Erickson, General Manager, 6120 Osseo Road, Minneapolis 55429. Phone 561-3590 or residence 533-7332.

PLAINVIEW, MINNESOTA needs two doctors. Town serves 12,000. Facilities: 3-year-old medical clinic and 70-bed nursing home with emergency facilities. Contact: John Peterson, % P.A.I.C., 740 Third Avenue N.W., Plainview.

BEAUTIFUL NEW OFFICE available now for second office or solo practice. Wonderful opportunity, progressive area, only specialists in area now are OB-GYN. Excellent lease arrangement. Look into this! Write: MINNESOTA MEDICINE — 375, 496 Lowry Medical Arts Building, St. Paul 55102.

EASTERN WISCONSIN CLINIC in rapidly growing community of 50,000 desires board-eligible or certified physicians in obstetrics and gynecology, pediatrics, orthopedic surgery, urology and otolaryngology. Well-equipped clinic and excellent hospital facilities. Lake shore location offers ample recreational facilities. Attractive financial plan leading to early full partnership. Full expenses paid for applicants invited to interview. Call or write: F. L. Hildebrand, M.D., Riverside Clinic, Menasha, Wisconsin.

GENERAL PRACTITIONER seeks challenging, rewarding relocation; over ten years exceptional experience general-surgical practice. Capable — excellent references, health. Consider group, partnership, industrial, emergency practice. Full details first letter. Write: MINNESOTA MEDICINE — 380, 496 Lowry Medical Arts Building, St. Paul 55102.

GENERAL PRACTITIONER — MINNESOTA STATE PRISON. Serve as Medical Director of 50-bed hospital with staff of registered nurses and laboratory technician. Surgical resident provided by University of Minnesota. Consultant service in various specialties also available. Fringe benefits included. Minnesota Civil Service Position. Contact: L. D. Jones, Box 55, Stillwater, Minnesota 55082 — Telephone 439-1910, Ext. 320.

THE S.S. HOPE is a floating medical center — a fully staffed and fully equipped modern hospital which is the vehicle by which Project HOPE fulfills its mission of carrying American medical treatment and training to foreign lands where such help is not only needed but wanted. Project HOPE is a nongovernmental, nonprofit organization which is financed solely by voluntary contributions from individuals and private enterprise of North America.

THEIR HOPE — Although thousands of natives are treated on ship and ashore, the primary objective of HOPE is teaching. Every HOPE physician, nurse, or technician has his local counterpart who is trained to continue modern treatment after the ship leaves. It is a seeding process which multiplies in the underdeveloped country to improve the health of its citizens and thus their productivity and thereby creates a progressive economy and a higher living standard. The kind of economy in which communism cannot thrive!

OUR HOPE — HOPE — an acronym for Health Opportunities for People Everywhere — is a young Project only in its fourth year of operation but already the evidence is incontestable that its missions are highly successful, not only in the interchange of medical knowledge but also in promoting international friendship and goodwill.

YOUR HOPE — HOPE's basic professional staff of nurses, technicians, etc., are paid a nominal salary but most of its teaching physicians and dentists serve without financial compensation. This makes it not only our most successful foreign aid program but also our cheapest. Nevertheless, private contributions are essential. You may participate by drawing and mailing a check to:

Cervical Lymphography

The Present Status

MELVIN E. SIGEL, M.D.*
Minneapolis, Minnesota

LYMPHOGRAPHY, A METHOD for study of the lymphatic system using radiopaque contrast agents, received its prime impetus in 1952 when Kinmonth described a method for lymph-vessel cannulization allowing insertion of contrast agents directly into the lymphatic system. The primary usefulness of this technique was in delineating lymphatic pathways of the upper and lower extremities as well as the retroperitoneal area.

In 1960 (Battezzati, Pietrantonì), techniques were developed for cannulization of the cervical lymphatic system allowing visualization of the cervical lymphatics and lymph nodes with water-soluble contrast agents. Further modifications and revisions in this technique, particularly the better-quality radiographs produced by oily contrast agents, demonstrated greater predictability in the study of the cervical lymphatic network (Jackson 1963).

Cervical Lymphatic Pathways

The excitement engendered by radiographic demonstration of the cervical lymphatics was understandable. Perhaps this method of study would supply acceptable answers to poorly-understood patterns of cervical lymph-node patterns. Also, pathways in the neck as well as cervical lymphatic routes sought by metastasizing carcinoma of the larynx, oral cavity, sinuses and other head and neck regions might be more readily studied. Alterations in lymphatic flow secondary to cervical malignancies, surgery on the head and neck and lymphatic changes brought about by x-ray therapy to the neck could perhaps be studied and evaluated with this direct and reproducible technique.

Technique

The technique, as modified by Fisch and

*Clinical Instructor, Department of Otolaryngology and Chief, Otolaryngology, Hennepin County General Hospital.

Bibliography available on request (801 Physicians and Surgeons Building, Minneapolis, Minnesota).

Fig. 1-a — Cervical lymphogram with good lymphographic-demonstration of the cervical nodes.

Fig. 1-b — Schematic representation of lymph nodes demonstrated by this method.

del Buono (1963) and further refined by Fisch and Sigel (1964), consists in administration of the oily contrast fluid, Lipiodol ultra-fluid, into a deep post-auricular lymphatic vessel using magnification afforded by the otomicroscope, following which, x-rays of the injected site are taken.

Observations

To date, certain observations may be attributed to this procedure of direct lymphatic cannulization and injection of contrast agents into the cervical lymphatic stream.

A demonstration of the normal lymphatic-flow pattern and lymph-node network comprising the deep lateral cervical lymphatic system with a functional classification of these lymph nodes by their lymphographic-filling characteristics into junctional, jugular, supraclavicular, spinal and retroauricular nodes has been possible (Figures 1-a and 1-b). Demonstration of the junctional group acting as a functional unit through which the spinal and jugular chains appear to fill has been of particular interest (Fisch and Sigel, 1964).

Changes in lymphatic flow-patterns brought about by surgical extirpation of cervical lymphatic tissue, such as in radical neck dissection, have been studied, demonstrating lymphographically a block to lymphatic flow at the resected sites with the lymphatic channels seeking alternate (including contralateral) drainage pathways (Sigel and Fisch, 1965).

Changes in the lymphatic system brought about by x-ray therapy to the neck have been evaluated, demonstrating continued though diminished flow through these radiated lymphatics and lymph nodes.

The most hoped-for clinical use of cervical lymphography, that is, the detection of non-palpable lymphatic metastases by lymphangiographic methods, has been partially stymied by the observation that non-specific lymph-node reactions, such as lymphoid and reticular hyperplasia, may give lymphographically-similar radiographs to those seen with metastatic disease (Fisch, 1964).

Conclusions

At the present time, cervical lymphography is still most readily applicable in an experimental setting due at least in part to the difficulty of the technique. However, any system of study which so clearly demonstrates the lymphatic system as does lym-

phangiography must be considered to hold great promise; and further refinements in technique as well as new contrast agents may eventually yield in cervical lymphography a valuable tool for the study of metastatic pathways in malignant disease of the head and neck.

King Charles II at the Mercy of His Doctors

Some idea of the nature and number of the drug substances used in the medicine of the past may be obtained from the records of the treatment given King Charles II at the time of his death. At eight o'clock on Monday morning of February 2, 1685, King Charles was being shaved in his bedroom. With a sudden cry he fell backward and had a violent convulsion. He became unconscious, rallied once or twice, and after a few days died. Seventeenth-century autopsy records are far from complete, but one could hazard a guess that the king suffered an embolism or else his kidneys were diseased. As the first step in treatment the king was bled to the extent of a pint from a vein in his right arm. Next his shoulder was cut into and the incised area "cupped" to suck out an additional eight ounces of blood. After this homicidal onslaught the drugging began. An emetic and purgative were administered, and soon after a second purgative. This was followed by an enema containing antimony, sacred bitters, rock salt, mallow leaves, violets, beet root, camomile flowers, fennel seed, linseed, cinnamon, cardamon seed, saffron, cochineal, and aloes. The enema was repeated in two hours and a purgative given. The king's head was shaved and a blister raised on his scalp. A sneezing powder of hellebore root was administered, and also a powder of cowslip flowers "to strengthen his brain." The cathartics were repeated at frequent intervals and interspersed with a soothing drink composed of barley water, licorice and sweet almond. Likewise white wine, absinthe and anise were given, as also were extracts of thistle leaves, mint, rue, and angelica. For external treatment a plaster of Burgundy pitch and pigeon dung was applied to the king's feet. The bleeding and purging continued, and to the medicaments were added melon seeds, manna, slippery elm, black cherry water, an extract of flowers of lime, lily-of-the-valley, peony, lavender, and dissolved pearls. Later came gentian root, nutmeg, quinine, and cloves. The king's condition did not improve, indeed it grew worse, and in the emergency forty drops of extract of human skull were administered to allay convulsions. A rallying dose of Raleigh's antidote was forced down the king's throat; this antidote contained an enormous number of herbs and animal extracts. Finally bezoar stone was given. Then says Scarburgh: 'Alas! after an ill-fated night his serene majesty's strength seemed exhausted to such a degree that the whole assembly of physicians lost all hope and became despondent: still so as not to appear to fail in doing their duty in any detail, they brought into play the most active cordial. As a sort of grand summary to this pharmaceutical debauch a mixture of Raleigh's antidote, pearl julep, and ammonia was forced down the throat of the dying king.'

King Charles was helpless before the drugging of his physicians, who wished to leave no stones unturned in his treatment.*

*Haggard, Howard W.: *Devils, Drugs, and Doctors*. Blue Ribbon Books, Inc., New York City, 1929, p. 334.

Minnesota Medicine at a Glance

Research in Otology — Lawrence

Page 813

From the first awareness that aerial vibrations were involved in the production and transfer of sound 400 years ago to the development of modern surgical techniques for the correction of deafness due to otosclerosis, the sequence of experimental study presents a long and interesting history. To otologists the field is still wide open for further advancement.

Otosclerosis — House

Page 817

Within the past ten or twelve years surgery for hearing loss due to otosclerosis has proven to be satisfactory in a high percentage of cases. The physical technique is not beyond the ability of one who has been adequately trained; therefore this procedure offers an opportunity for many individuals to receive improved hearing function.

Management of Acoustic Tumors — House and Hitselberger

Page 873

Surgical techniques used to remove acoustic tumors have been developed and a system of operations is now available to remove these tumors at every stage of their development without a disproportionate increase in surgical mortality.

Adenotonsillectomy — Donaldson

Page 933

Too frequently adenotonsillectomy has been used without adequate indication. Reasonably well controlled studies indicate that adenotomy rather than adenotonsillectomy is indicated for recurrent acute otitis media and recurrent middle ear fluid. The indications for tonsillectomy vary with age.

Bell's Palsy — Shambaugh

Page 985

Though Bell originally recognized the effect of trauma in causing paralysis of the seventh nerve, most of the instances of Bell's palsy have been considered to be idiopathic, despite the fact that 70% of the cases revealed a history of abnormal cooling of the mastoid region. The rigid confines of the facial nerve within the fallopian canal makes it possible for compression to result from edema, with blocking of the electrical conductivity and the nerve impulses. With electrical stimulation it is possible to determine a normal excitability of the nerve or a progressive reduction in the nerve excitability, which would then signalize the need for operative reduction of the area of compression.

Episodic Vertigo — Williams

Page 1008

Episodic vertigo presents an annoying diagnostic problem often enough to give the clinician episodes of causalgia. In order to understand the problem more thoroughly, Williams has enumerated many, described some of the causative factors, and suggested varieties of treatment which have been used to ameliorate these symptoms. He points out that if it proves impossible to differentiate between the more probable etiologic factors by history and functional tests, a series of treatments, each based on a different working hypothesis, should be tried in order to find out from the therapeutic results which of such working hypotheses is the more correct. With this plan of attack, it should nearly always be possible to provide symptomatic relief to a number of disorders whose only connecting links are principally the symptoms of vertigo, dizziness or both.

Psychosomatic Turmoil in the Ear — Hoople

Page 1025

Though the stomach may be the major target for psychosomatic symptoms, the ear falls not far behind. Most of the subjective psychosomatic symptoms are manifest as itching, tinnitus, impaired hearing, and dizziness. The physician should take time to solve the psychosomatic puzzles.

Darwin to Lyell

Our ancestor was an animal which breathed water, had a swim bladder, a great swimming tail, an imperfect skull, and undoubtedly was an hermaphrodite! Here is a pleasant genealogy for mankind. . . . I take a jealous pride in my Simian ancestry. I like to think that I was once a magnificent hairy fellow living in the trees, and that my frame has come down through geological time via sea jelly and worms and Amphioxus, Fish, Dinosaurs, and Apes. Who would exchange these for the pallid couple in the Garden of Eden?

— Charles Darwin

Send in your 35 mm color slides to MINNESOTA MEDICINE for the Cover Contest. Each month the winner's picture will be published in full color on the cover of MINNESOTA MEDICINE.

after surgery

B and C vitamins are therapy: Therapeutic amounts of B and C in stress formula vitamins often are vital during periods of physiologic stress. STRESSCAPS capsules, designed to meet increased metabolic demands, aid in achieving a more comfortable convalescence, a more rapid recovery. After surgery, as in many stress conditions, STRESSCAPS vitamins are therapy.

Stresscaps®

Stress Formula Vitamins Lederle

Each capsule contains:

Vitamin B ₁ (Thiamine Mononitrate)	10 mg
Vitamin B ₂ (Riboflavin)	10 mg
Vitamin B ₆ (Pyridoxine HCl)	2 mg
Vitamin B ₁₂ Crystalline	4 mcgm
Vitamin C (Ascorbic Acid)	300 mg
Niacinamide	100 mg
Calcium Pantothenate	20 mg

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, New York

627-6-3613

LIBRIUM[®] (chlordiazepoxide HCl)

WHEN ANXIETY IS A SIGNIFICANT COMPONENT OF THE CLINICAL PROFILE

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Warn against hazardous occupations requiring complete mental alertness. Use caution in administering to addiction-prone patients or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of child-bearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In elderly and debilitated and in children over five, limit dosage to smallest effective amount, increasing gradually as needed and tolerated. In general, concomitant use with other psychotropics is not recommended. Paradoxical reactions have been reported in psychiatric patients and hyperactive aggressive children. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically. Observe usual precautions in presence of impaired renal or hepatic function, impending depression and suicidal tendencies.

Adverse reactions: Drowsiness, ataxia and confusion may occur, especially in elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. Syncope occurs rarely. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis, jaundice and hepatic dysfunction) may develop occasionally, making periodic blood counts and liver-function tests advisable during protracted therapy. Individual maintenance dosages should be determined.

Dosage: Oral—Adults: Mild to moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d.

Supplied: Capsules, 5 mg, 10 mg and 25 mg—bottles of 50.

In peptic ulcer... antacid therapy with a new benefit

CONTAINS A BALANCED
COMBINATION
OF THE MOST WIDELY
USED ANTACIDS—
FOR RAPID
NEUTRALIZATION.
PLUS SIMETHICONE—
TO CONTROL
THE FACTOR WHICH
ANTACIDS ALONE
CANNOT INFLUENCE.

Mylanta®

- In Mylanta, aluminum and magnesium hydroxides are balanced to minimize the chance of constipation or laxation and still achieve rapid acid neutralization and pain relief.
- The positive action of simethicone helps relieve the painful gas symptoms which often accompany the peptic ulcer syndrome.
- The nonfatiguing flavor and smooth, nongritty consistency of tablets and liquid encourage continued patient cooperation during long-term therapy.

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) of liquid contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. **Dosage:** one or two tablets, well chewed or allowed to dissolve in the mouth, or one or two teaspoonfuls of liquid to be taken between meals and at bedtime.

Valium
(diazepam)
Roche®

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Infants, patients with history of convulsive disorders or glaucoma.

Warning: Not of value in the treatment of psychotic patients, and should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly patients (not more than 1 mg, one or two times daily) to preclude ataxia or oversedation. Advise patients against possibly hazardous procedures until correct maintenance dosage is established; driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended; Warn patients of possible combined effects with alcohol. Safe use in pregnancy not established. Observe usual precautions in impaired renal or hepatic function and in patients who may be suicidal; periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side Effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances, hallucinations); changes in EEG patterns. Abrupt cessation after prolonged over-dosage may produce withdrawal symptoms similar to those seen with barbiturates, meprobamate and chlor-diazepoxide HCl.

Dosage—Adults: Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 to 10 mg t.i.d. or q.i.d. Geriatric patients: 1 or 2 mg/day initially, increase gradually as needed.

Supplied: Tablets, 2 mg, 5 mg and 10 mg; bottles of 50 for convenience and economy in prescribing.

some allergens are green

whatever their color,
shape, or size...

Benadryl[®]

(diphenhydramine hydrochloride)

PARKE-DAVIS

for control of
allergic symptoms

Whether the allergen is greenish or garish, unseen or unknown, your patient can get symptomatic relief with BENADRYL—the potent antihistamine with antispasmodic action. **INDICATIONS:** Antihistaminic, antispasmodic, antitussive, and antiemetic therapy.

PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers if used with diphenhydramine hydrochloride should be prescribed with caution because of possible additive effect. Diphenhydramine

has an atropine-like action which should be considered when prescribing diphenhydramine hydrochloride. **ADVERSE REACTIONS:** Side effects are generally mild and may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, blurring of vision, vertigo, headache, muscular aching, thickening of bronchial secretions, restlessness, and insomnia have been reported. Allergic reactions may occur.

BENADRYL is available in Kapseals[®] of 50 mg. and Capsules of 25 mg.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in

this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Picture of bursitis

**Parafon Forte helps to relieve pain,
restore mobility . . . stop pain-spasm feedback**

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 6-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.
Tylenol® (acetaminophen) 300 mg.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light-headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied:** Scored, light green tablets, imprinted "McNEIL"—bottles of 100.

President's Letter

TRIBUTE SHOULD be paid to a dedicated group of people doing a fantastic job for the medical profession and the general public here in Minnesota. Their efforts are unique. I would recall your attention to a special article which appeared in the June, 1966, issue of MINNESOTA MEDICINE having to do with the work of the Pre-School Medical Survey of Vision and Hearing. Acknowledgement was made in that article of the tremendous work which a very gracious lady by the name of Mrs. John R. Stoltze has done in stimulating this rapidly developing program.

Dr. R. Hugh Monahan and his Committee on Ophthalmology sparked the whole effort and, with representatives of the Committee on Conservation of Hearing, the Survey was incorporated in 1959. Mrs. Stoltze was named executive secretary. The entire program is sponsored by the MINNESOTA STATE MEDICAL ASSOCIATION and administered by a Board of Directors composed of members of these Committees. The Survey is incorporated so as to receive gifts and gets its support from three sources: donated funds (which are deductible), the MS-MA, and temporary support from a Federal grant.

After 1959, when the program was started, it took two years for a group of audiologists under the direction of Dr. K. M. Simonton to develop a screening device called the Verbal Auditory Screen for Children (VASC). In 1961, the first full year of testing, only 1546 children could be tested, because of a lack of screeners as well as equipment. In 1966, by contrast, it had become possible to test 14,515 children.

The task ahead is enormous, but the way these people work makes a tremendously interesting story. Their goal is to be able eventually to test

all of the four-year-olds in the state, which number between 70,000 and 75,000 children. At the present time there are 35 "demonstrators." These are specially trained women, volunteers, usually housewives, including physicians' wives, Mrs. Jaycees, and other community-minded women, who do the job of training the screeners.

Over the state there are now about 4,500 screeners, and their numbers are growing rapidly each year, who will eventually be able to do the job they have set for themselves. They hope to double the number of children tested in 1967 over the 14,515 figure of last year. Eighty percent of the medical reports received have been positive, a remarkable testimonial to the equipment which has been devised, and certainly to the efforts of all those involved in the program.

This entire task has of necessity grown slowly at first, but now it seems to be snowballing to the point where their goal will be reached within a very few years. These service clubs, who have been sponsoring this effort, the Woman's Auxiliary to the Minnesota State Medical Association, the PTA's, the Mrs. Jaycees, Jaycees, Lions, Kiwanis, Rotary, hospital auxiliaries, and many others should be given our great vote of thanks for the work they are doing for our children.

Whenever the program is started in a community, the physicians should be wholeheartedly behind it, for without these trained lay people doing the job, it could never be done.

Cystic Fibrosis

Nature

and

Prognosis*

WARREN J. WARWICK, M.D.**

Minneapolis, Minnesota

ALTHOUGH CYSTIC fibrosis is a fatal disease, it may be compatible with a normal life if adequate treatment is started early. We can resolve this paradox by considering the relationship of the inherited metabolic defect to the complications which form the syndrome recognized by clinicians as cystic fibrosis.

Clinical Manifestation

The clinician sees cystic fibrosis as a chronic pulmonary disease with pancreatic insufficiency and an increased amount of salt in the sweat. He suspects the diagnosis in infants and young children who gain weight poorly, have steatorrhea, develop rectal prolapse, acquire a persistent cough, pulmonary atelectasis or multiple pulmonary infections. He confirms his suspicion on the basis of a sweat chloride or sodium in excess of 60 meq/L. His clinical experience has taught him that death is likely to occur in a few years even if he uses many antibiotics for treatment and prophylaxis of infections as well as pancreatic enzymes to control the bowel symptoms and a high vitamin and protein diet to prevent deficiencies.

Abnormal Exocrine Glands

How then may a normal life be possible? To understand this contradiction we must arbitrarily distinguish the inherited metabolic defect from the clinical syndrome. The inherited defect is transmitted by a single gene on an autosomal chromosome and is present in every fetus who receives such a gene from both parents. The direct consequences of the inherited genetic defect is the formation of abnormal exocrine glands and the elaboration of abnormal secretions. The clinical syndrome is the result of complications

*USPHS Research Career Development Awardee K3-A5, 14,035

This research was supported by a Cystic Fibrosis Care, Research and Teaching Center grant from the National Cystic Fibrosis Research Foundation and a grant-in-aid from the Minnesota Cystic Fibrosis Chapter.

**Associate Professor of Pediatrics University of Minnesota Medical School.

caused by the abnormal secretions. A normally active life may be possible if prophylactic therapy can be used to prevent or to delay the onset of the potential complications.

Effects of Salt Depletion

The sequence from the inherited defect to the clinical complications and the prophylactic treatment necessary to prevent the complications is seen most clearly in the pathophysiology of the sweat gland. The nature of the defect is unknown, but the secreted sweat is recognized to be abnormal by the increased content of sodium and chloride. Clinical symptoms of salt depletion may develop after severe or prolonged sweating or a restriction of salt intake. Prostration, shock, and death may result. Prophylactic treatment, consisting of an increased amount of salt in the diet, will prevent these complications.

Pulmonary Complications

The sequence from the primary defect in the mucous glands to the pulmonary complications is similar but more complex, the complications more frequent and serious and the prophylactic treatment less well established. The nature of the mucous gland defect is also unknown, although the secretions of the mucous glands and goblet cells are abnormally viscous.

Bronchial Obstruction

Ciliary activity, increased velocity of expired air and coughing, which move normal bronchial mucus freely, are relatively ineffective in moving bronchial mucus in patients with cystic fibrosis. Thus, mucus accumulates and causes the first complications: partial bronchial obstruction with over-distention of/or total bronchial obstruction with collapse of the distal lung.

Infection

The lung handicapped by accumulating mucus is susceptible to infection, since bacteria entering the lung are normally trapped in mucus and expelled. The stagnant mucus in patients with cystic fibrosis permits bacteria to grow and to cause local infection. Infection in turn causes leukocytic and serum exudation and formation of intrabronchial pus, thus increasing the quan-

tity and viscosity of the retained secretions. The inflammation induced by the infection causes hypertrophy of the mucus-secreting glands and cells and loss of ciliated cells. Untreated, the process is progressive, culminating in bronchial destruction, pulmonary insufficiency, cor pulmonale and death.

Mortality

Since the abnormal mucus in the bronchial tree causes 99 per cent of the morbidity and 95 per cent of the mortality in children with cystic fibrosis, the prognosis for survival can be estimated by sole consideration of the pulmonary complications if the mortality caused by meconium ileus is ignored. Three assumptions are pertinent for this consideration. First, the earlier the treatment is started after symptoms begin, the longer the severe complications can be delayed. Second, if treatment can be devised to delay the onset of complications, prognosis should be further improved. Third, if the abnormal secretions could be made normal or the glandular defect corrected, a normal life would be possible. The first and second assumptions are supported by life tables made for children with cystic fibrosis receiving different types of treatment.

Generation Life Table

The life table approach makes it possible to summarize mortality rates for specific populations at specific periods and to obtain measures of comparative longevity such as the median length of life after birth or the proportion of persons surviving to specific ages. There are two types of life tables: the generation or cohort life table and the current life table. The "generation life table" provides a "longitudinal" perspective in that it follows the mortality experience of a particular cohort, all persons born in the year 1900, for example, from the moment of birth through consecutive ages in successive calendar years. Based on age-specific mortality rates observed during consecutive calendar years, the generation life table reflects the mortality experience of a cohort from birth until no lives remain in the group.

Current Life Table

The better known "current life table" may, by

contrast, be characterized as cross-sectional. Unlike the generation life table, it does not represent the mortality of an active cohort. Rather, the current life table considers a hypothetical cohort and assumes that it is subject to the age-specific mortality rates observed for an actual population during a particular period. Thus, for example, a current life table for 1960 assumes a hypothetical cohort subject throughout its lifetime to the age-specific mortality rates prevailing for the actual population in 1960. The current life table may thus be characterized as rendering a "snapshot" of current mortality experience.¹

When the limiting data for the cohort populations has been defined, comparisons can be made. The Figure shows survival curves for several cohort populations of patients with cystic fibrosis which were prepared from life table data. Curve G shows the life table curve for the whole United States population based on age-specific mortality rates for 1960. Curve A demonstrates the early onset and the malignant nature of cystic fibrosis as recorded in three reports published in 1938.^{2,3,4} This curve includes five patients diagnosed at the University of Minnesota prior to 1938.* No treatments were used prior to 1939, which would have altered the natural history of the complications of cystic fibrosis in these patients. The significant points to note in this representation of the natural mortality of cystic fibrosis are: (1) the median age at death was eight months of age; (2) over 70 per cent of infants died before age one; but (3) an occasional child survived beyond 10 years of age.

Treatment

After 1939 when sulfanilamide and antibiotics became available, treatment could be directed at pulmonary infections.

Antibiotic Medication

Two reports plus the records of the University of Minnesota Hospitals were complete enough to calculate life tables. The patients in these three studies received antibiotic treatment for pulmon-

ary infections and supportive measures including pancreatic enzyme replacement.^{5,6,7} Curves B, C and D show improved survival but great variation in the amount of improvement. If the two better curves are taken to be most representative of the improved prognosis for children with cystic fibrosis who received sulfa and antibiotic treatment, we observe that: (1) the median age at death increased to three years; (2) the proportion dying before age one decreased from over 70 to about 36 per cent; (3) survivors beyond age 10 increased from an occasional patient to nearly 10 per cent.

Pulmonary Hygiene

In the 1950's intensive pulmonary treatment, in particular aerosols by face mask and mist tent and physical therapy to the chest wall and lungs, began to be used to remove retained secretions from the lungs. These techniques form the basis for the present treatment of cystic fibrosis in Cystic Fibrosis Care, Research and Teaching Centers throughout the United States.⁸ Many variations are currently in use. In 1965, 31 of these Cystic Fibrosis Centers pooled data on the patients they followed and the deaths they observed in 1964.⁹ These data are shown in Curve E. In this cohort the improvement in survival is obvious: (1) the median age at death is shown to be 12 years; (2) the proportion dying before age one decreased to 11 per cent, and (3) survivors beyond age 20 increased to nearly 30 per cent.

Figure

*C.H. born November, 1933; died January, 1934—age 3 months
G.P. born October, 1934; died January, 1935—age 3 months
T.P. born July, 1937; died May, 1938—age 10 months
N.G. born August, 1937; died October, 1937—age 2 months
D.H. born October, 1937; died March, 1938—age 6 months

Results

The pulmonary therapy used at these 31 Centers was begun at varying times. Some Centers started pulmonary therapy prophylactically^{10,11} as soon as the diagnosis was made, with the advocated purpose of preventing or delaying the onset of the obstructive and infectious pulmonary complications. If prophylactic pulmonary therapy is of value, the survival curve for patients given this therapy should be better than the average pulmonary which is usually delayed until the obstructive and infectious pulmonary complications have begun. In the Figure, Curve F shows the survival curve for all patients with cystic fibrosis cared for at Babies and Children's Hospital, Western Reserve University, since the Cleveland Cystic Fibrosis Center was organized.¹² All patients seen between 1958 and 1966 including those diagnosed at autopsy are included. Patients seen once for consultation were excluded in order not to give a falsely good curve. The improvement in survival for this cohort appears to be significant: (1) the median age at death is estimated to be 21 years; (2) the proportion dying before age one is 4.3 per cent as compared to 2.3 per cent for the whole U.S. infant population in 1960; and (3) survivors beyond age 20 increased to over 50 percent.

In this group 24 deaths occurred in the 349 children under care for a total of 1,188 patient years. The children were followed for an average of three years five months. None were followed for more than eight years. The mortality at any point along Curve F after age four reflects the mortality for children diagnosed on the average three and one-half years earlier. In the early years of the curve when few complications were present at diagnosis and maximal benefit from prophylactic therapy could be expected, death, the ultimate complication, was frequently prevented. In the last part of the curve when more and severer complications were present in patients admitted to the study and less benefit could be expected, death occurred as frequently as in the last years of Curve E for the averaged pulmonary therapy.

Although more data will have to be collected

to separate and compare the value of prophylactic versus symptom-directed pulmonary therapy, survival with the prophylactic approach appears to be improved. Data such as these require confirmation by other centers* and warrant carefully controlled studies of morbidity as well as of mortality. However, continued collection and tabulation of mortality data on patients with cystic fibrosis treated at Cystic Fibrosis Centers will permit annual computation and comparisons of survival, longitudinal studies of cohorts of patients born in one year and diagnosed at different ages, and eventually comparison of therapies.

Evaluation of therapies by the life table technique reviewed in this paper is subject to few criticisms other than overt falsification of data, for death is a criterion universally acceptable for failure of a treatment program. However objective death is as an absolute criterion, it is not sensitive to subtle differences in the values of therapy, and vast amounts of mortality data would have to be collected, perhaps over extended years, to pinpoint that type of difference. Such a use of the life table technique would be either insensitive to, or biased by, inability to keep therapy constant over long periods of time. Comparison of therapies by the life table mortality end-point is not to prove one therapy better than another but to identify aspects of therapy which need carefully designed and controlled studies and to supply the stimulus to evoke these studies. This comparison of averaged pulmonary therapies vs. prophylactic pulmonary therapy suggests that controlled studies are needed to evaluate the philosophy and the specific components of the prophylactic approach to the pulmonary disease in children with cystic fibrosis.

Conclusions

Controlled studies of morbidity in matched newborn infants with cystic fibrosis appear to be the best way to evaluate the prophylactic approach. This need is now stimulating studies which may one day produce a practicable newborn nursery sweat test for cystic fibrosis.¹³ The aims of research beyond such a study are to find ways to directly normalize the mucus as it is being formed or to modify the cells of the mucous glands so that they will produce normal mucus. When either is achieved, patients with cystic fibrosis who do not have pulmonary complications should be able to live lives freed from

*Annual crude mortality rates for patients with cystic fibrosis treated at the University of Minnesota were: 1958—23.5%; 1959—29.2%; 1960—20%; and 1961—15.4% before starting prophylactic pulmonary therapy. Since then the rates have been: 1962—16.2%; 1963—3.2%; 1964—2.8%; and 1965—2.2%.

their present increased predisposition to bronchial obstruction and infection; then the goal of

prophylactic therapy, a normal healthy life, may be achieved.

LEGAL MEDICINE INSTRUCTIONAL PROGRAM

Summer Instructional Program on "Legal Medicine and Elements of Medico-legal Litigation," for Trial Lawyers and Physicians. Lecture each morning, 8:00-12:25 noon, leaving afternoons open for family vacation activities.

Place:

Crested Butte, Colorado, in the beautiful Rocky Mountains of Gunnison National Forest, 24 miles from Aspen.

Program:

Esteemed Trial Lawyers and medical experts, including those in audience, help develop applied Medicolegal Problems and Medicolegal Trial Technique by floor repartee and discussion. Six independent, self-contained, weeks:

Mon.-Fri., July 10 to Aug. 18, 1967.

Family members may attend sessions without additional registration fee.

Rates:

Housing per week—\$66 double, \$14 for each child.

Registration Fee—\$75.

Host Lodge:

The Crested Butte Lodge at new Ski Area.

For details write to the Director: Hubert Winston Smith, LL.B., M.D., Chancellor, The Law-Science Academy of America, Crested Butte, Colorado 81224.

On studying the development of human intelligence, it is found that it passes through three stages: the theological, the metaphysical, the scientific or positive. In the theological stage it seeks to account for the world by supernatural beings. In the metaphysical stage it seeks an explanation in abstract forces. In the scientific, or positive, it applies itself to the study of the relation of phenomena to each other. At present the theological, the metaphysical and the positive conflict, and cause intellectual confusion. — Auguste Comte

Faith

MAN is a whole being; he cannot be divided into parts; he is not a jig-saw puzzle; he is a one-piece person. The patient is physical; he is spiritual; he is mental; and he is social in his total health. It is widely recognized that a weakness in any one of the four factors of his health can militate toward ill health in any one or all three of the other factors. We recognize immediately that all illness is not organic. The parents of the retarded child in some cases are more ill than is the child. Moments of shock, fear, hysteria, and grief are moments of serious illness and these illnesses can affect the whole being.

The faith of the individual is a vital factor in total health. The patient must be treated and cared for within the scope of that faith, because it is faith that gives courage, strength, patience, assurance, and hope—all of which aid in the healing process. These are not commodities that can be purchased in a bottle at the drug store but are intangible factors underlying every individual's basic philosophy of life and hence his total health.

Too frequently our illnesses are not organic ones that can be mitigated or cured by drugs; nor are they diseased areas that can be removed by a surgeon's knife. Instead, our illness requires therapy deep within our heart and our life. Because of the stress and strain exerted by the pressures and demands of the world, either we have forgotten that faith plays a vital and important role in our total well-being or we have thoughtlessly forsaken that faith.

To what extent do we maintain the patient as a mere vegetable? The practice of euthanasia or mercy killing is not involved here; medicine as a profession is opposed to both. The physician and the clergyman need to have dialogue in this area: they need to discuss this issue carefully—with understanding, compassion, and mercy, so that the physician can be assisted in making his decision a scientific and at the same time a moral one.

A person has the right to die with the dignity inherent in death itself. I question the use of extreme measures to prolong a merely vegetating life. With mechanical means we can sustain the beating heart; but is this life in the true sense? To allow a body to waste away to nothing but skin and bone is to refuse the human being his prerogative of dignity in death.

Herein lies the paradox of modern medicine: the fact that we have facilities and techniques to prolong and save lives; but that these same procedures can also be used to prolong mere existence.

A young teenage lad was seriously injured, resulting in total paralysis from the waist down. A mother and a father who had hoped and planned for their son's future now saw all their dreams tragically shattered. The young man himself who had lived day by day, full of ambition, energy, enthusiasm, now finds all these sparks extinguished. A wheelchair is to be his home. Where, I ask, do we turn to give this man the incentive to live?

Here then is the sphere of interplay between physician, clergy and family—the challenge to make this young man see that life is more than a pair of legs—that despite physical handicap, life can still be a wonderful adventure. It takes more than a drug, more than a surgeon's knife, even more than the love and compassion of a family. It demands faith!

|| Amniocentesis

Effect
of
Contamination
of
Amniotic
Fluid
with either
Maternal
Blood
or
Meconium

WILLIAM N. SPELLACY, M.D.*
W. D. COHEN, Ph.D.*
R. A. DIAMOND, M.D.*
Minneapolis, Minnesota

ONE OF THE MORE recent advances in the management of the Rh negative sensitized pregnant subject has been the introduction of studies of the amniotic fluid pigments. Of all available tools to the clinician this seems to have the best prognostic value. The procedure of amniocentesis^{oo} is safe. One not infrequent problem, however, has been the contamination of the amniotic fluid with maternal blood during the procedure, or the so-called "bloody tap." Another common contaminating substance is meconium. The effect of these substances in subsequent amniotic fluid analysis has not been well studied. The present study was undertaken in order to determine the changes produced in amniotic fluid pigment determinations by the injection of maternal blood into the amniotic cavity or from the addition of meconium to amniotic fluid.

Procedure

The patient was enrolled in the prenatal clinic at the University of Minnesota Hospitals and volunteered for this study. She was a 19-year-old gravida whose expected date of confinement was January 29, 1966. The patient's medical history was complicated by the presence of a congenital heart lesion which had been diagnosed as Ebstein's anomaly. Her cardiac history will be presented elsewhere. She had a serum bilirubin of 0.1 mgm. % at one minute and 0.3 mgm. % total. Her blood type was O CcDEe with a negative indirect Coombs test.

On 11/17/65, at 29 weeks of gestation, an amniocentesis was performed. After a fluid sample was removed for study, 10 ml. of the patient's blood was removed from an antecubital vein and injected into the amniotic (fluid) cavity. The patient had no adverse reaction to this procedure. Repeat amniocenteses were then performed on 12/2/65 (31 weeks of gestation); 12/16/65 (33 weeks of gestation); 12/30/65 (35 weeks of gestation), and 1/25/66 (39 weeks of gestation). The fluid samples were protected from light and immediately centrifuged at 2000 r.p.m. for 30 minutes to remove red cells and larger particles of vernix caseosa, and the supernatant was then filtered through retentive filter paper. The filtrate was then removed and the optical density was measured on a Beckman spectrophotometer

model B (calibrated for wavelength and photometric accuracy) between 325 and 700 millimicrons wave length. A chemical analysis of the supernatant bilirubin content was also done by the method of MacKay and Watson'. The results of the spectrophotometric and chemical analysis of these fluid samples are listed in Table 1.

TABLE 1

Changes in the Amniotic Fluid Pigments Produced
by the Introduction of Maternal Blood into the Amniotic Sac

PIGMENT STUDIED mgm %	CONTROL				
Methemalbumin of 625 mμ	0.03	0.31	0.18	0.02	0.28
Oxyhemoglobin of 415 mμ	0.83	1.82	0.73	0.96	1.76
Liley Units of Excess OD of 450 mμ	0.050	0.000	0.028	0.011	0.015
Chemical Diazo Bilirubin	0.057	0.046	0.031	0.000	0.045
	29	31	33	35	39
	WEEKS OF GESTATION				

The patient began labor spontaneously on 1/28/66, and after a total labor of 14 hours and 25 minutes she delivered a 3100-gram normal male infant over a left mediolateral episiotomy with the aid of low forceps and using paracervical and pudendal block anesthesia. The cord blood studies showed a hemoglobin of 17.5 grams %, and a one-minute bilirubin of 0.2 mgm. % with a total bilirubin of 1.9 mgm. %. The baby blood type was O CcDee with a negative direct Coombs test. Both the mother and infant have done well post partum.

Discussion

The use of amniotic fluid pigments to predict the severity of erythroblastosis fetalis was pioneered by Bevis in 1953.² This procedure has been extensively studied now by Walker, Liley and others.³⁻⁵ Both the simplicity of the procedure of amniocentesis and the relatively accurate prognostic index of the spectrophotometric analysis of the amniotic fluid have determined the wide acceptability of this test. The two major drawbacks to this method are: (1) the maternal and fetal complications and (2) the occasional false-positive test results.

The false-positive fluid analysis can be disastrous if the studies predict a severely affected infant and if the obstetrician prematurely delivers a normal unsensitized infant. False-positive results have occurred.^{6,7} The explanation for the presence of these abnormal pigments is unknown.

The maternal and fetal complications of am-

niocentesis have been described by several authors and include failed taps, bowel perforation, amnioitis, fetal hemorrhage, abruptio placentae, premature labor, and hemoperitoneum.⁸⁻¹² Zippursky has also suggested that further sensitization of the mother occurs from the spillage of fetal red blood cells into the maternal circulation at the time of amniocentesis.¹⁰ The occurrence of these complications is rare, however.

A more frequently encountered problem is the "bloody tap," where maternal blood is spilled into the amniotic cavity during amniocentesis.

The present study was undertaken in order: (1) to better understand the changes in the spectrophotometric analysis of amniotic fluid after maternal blood is accidentally put into the amniotic cavity and (2) to try to find a cause of the false-positive amniotic fluid analysis.

The results of this experiment show that oxyhemoglobin (415 mμ) and the methemalbumin (625 mμ) concentrations rise abruptly after the blood contamination. The major indicators of fetal Rh disease, the excess optical density (O.D.) at 450 mμ (Liley units) and chemically determined bilirubin, are not affected by the "bloody tap." The fluid pigments return to a normal state in approximately four weeks. Liley has noted that the pigments from traumatic tap disappear by three weeks.⁸ These results show that the false-positive test results are apparently not due to maternal hemorrhage into the amniotic cavity.

With the use of intrauterine exchange transfusion as a treatment for affected infants these data demonstrate that one may contaminate the amniotic fluid with blood and still be able to use the results of amniotic fluid withdrawn at subsequent examinations as a prognostic index for the fetus.

In the search for the cause of false-positive results meconium was studied. Fresh meconium

TABLE 2

Changes Produced in the Amniotic Fluid
Pigments by the Addition of Meconium

	Pigments in mgm%			
	Methemalbumin 625 mμ	Oxyhemoglobin 415 mμ	Chemical Diazo Bilirubin	Liley Excess O.D. 450 mμ
Control Amniotic Fluid	0.003	0.065	0.061	0.045
Control Amniotic Fluid plus 0.1% Meconium	0.77	2.54	0.073	0.057

was obtained at a breech delivery and a 1% suspension of this was made in 0.9% saline. To one of two aliquots of a normal amniotic fluid sample was added a 0.1% concentration of meconium. Both fluids were then subjected to complete analysis as previously described. The results of this experiment are recorded on Table 2. Here also there is no significant alteration in the two prognostic indices for erythroblastosis (chemical bilirubin and Liley excess O.D. units). The meconium contamination of amniotic fluid does not cause a false-positive interpretation in the management of an Rh sensitized pregnancy.

Summary

Maternal blood was placed in the amniotic cavity at 29 weeks of gestation and amniocentesis was repeated on four subsequent occasions. The pigments resulting from this procedure are described. There is no increase in the principal pigments used as prognostic indices for erythroblastosis fetalis. Normal amniotic fluid was also studied with and without the addition of meconium. The pigment alterations produced by this are described. The significance of these findings is discussed.

Our Stone-Age Peers

Let us not regard paleolithic man with contempt. We are heirs to centuries of science, and as we think of modern man's absorption in war, of the grade of intelligence exhibited in political campaigns, of the various religious cults which sprang up within recent years, of the quality of periodicals with the largest circulation, of the seances of spiritualists in all countries, of the numerous individuals who earn a livelihood by reading palms and casting horoscopes, we realize that we have little reason to be boastful.

Shall we laugh because the medicine-man, in order to increase his dignity, smeared his body with red paint? Let us rather recall that in the civilized centuries the mark of the physician was a red cloak. Shall we mock his magic stick, the mere sight of which made his people feel better? Not as long as we remember the vogue of its successor, the gold-headed cane. Shall we condemn him because he sought to mystify his patients with wonder-tricks and words they could not understand? Let us reflect on more modern practitioners who give detailed instructions about taking a cathartic pill. In all ages, the invalid quite as much as the attendant, has insisted on a certain amount of hocus-pocus with the treatment.

Intellectually, we are but a stone's throw from the Stone Age; and emotionally, we are still living there.*

*Victor Robinson, *The Story of Medicine*, 1931.

Laughing Gas

Everything necessary to scientific anesthesia was available for some time before its "discovery," waiting for someone to stumble across it and put it to use. And that, literally, is just about how it happened, through staggering and stumbling.

Sir Humphrey Davy had suggested the anesthetic use of nitrous oxide after he had tried it on himself and found that it had an intoxicating effect, making him feel lightheaded and lighthearted.

People disregarded Davy's anesthetic suggestion but took up the inhalation of nitrous oxide as a popular fad. It soon became fashionable to have "laughing gas" parties where people breathed nitrous oxide, or ether, which had a similar effect. It was a very amusing pastime. People inhaled the gas, became pleasantly intoxicated, staggered and stumbled about, talked foolishly, laughed loudly and lost some of their inhibitions.

The popularity of ether and "laughing gas" parties jumped the Atlantic and soon young people, especially students, had taken up the rage in the more populous areas of the Eastern seaboard of America. The whole business was so fascinating, especially because of its so-called "scientific" overtones, that patent-medicine peddlars and other itinerant showmen posing as "professors of chemistry" gave lectures and demonstrations which attracted the thrill-seekers and gullible in the small towns and villages of the countryside.

One such traveling showman was a tall young man of 18 with an incompleted preparatory school education. Decking himself out in a frock coat and a high hat, he proclaimed himself as "Dr. Coult of New York, London and Calcutta" and set out in 1832 to demonstrate the scientific wonders of "laughing gas."

With a home-made apparatus which he pushed about in a hand cart, he first toured the towns of Massachusetts, setting up in the public squares on market day and, after making a speech and demonstrating on himself, he would invite spectators to inhale the gas. These spectacles so amused the audiences that Dr. Coult often collected as much as ten dollars when he passed the hat.

The young man, as it happened, was raising money in order to be able to patent and produce a revolver he had developed. His name was really Samuel Colt of Hartford, Conn.

A skilled showman, he became part owner of a penny museum in Cincinnati, where he put on a laughing gas show in order to help raise funds for Canadian patents on his Colt revolver. This time he decided to hire some Indians to inhale the gas, hoping that the novelty would attract a large crowd. He was right. The museum was jammed with people, many of whom came armed in the morbid expectation that the Indians would go on a scalping rampage.

What actually happened came as a shock to all. The Indians, probably having inhaled too much gas, promptly fell asleep. Colt, fearing the crowd would think itself cheated of its thrills and start a riot, quickly called a local blacksmith to the stage and gave him a whiff of gas. The befuddled smith then began to chase Colt around the stage, knocking over the Indians and waking them in the process. This saved the show.*

Nodular Disorders of the Legs

CARL W. LAYMON, M.D.*
Minneapolis, Minnesota

NODULAR INFLAMMATORY lesions of the legs frequently pose diagnostic difficulties. Recognition of the various entities usually depends upon correlation of both morphologic and histopathologic features. The clinician may not be able to make a diagnosis without understanding the pathology and the microscopist may find that histologic features alone are inadequate.

Winkelman (1964)¹ included erythema nodosum, erythema induratum, nodular vasculitis, Weber-Christian disease and lipogranulomatosis subcutanea (Rothmann-Makai), pernio,** superficial thrombophlebitis, and periarteritis nodosa among the classic nodular lesions of the legs. He stated that in addition to these, several new nodular inflammations of the lower extremities have been recognized within the past two decades, such as nodular fat necrosis with pancreatic diseases, subacute migratory panniculitis, necrobiosis granulomatosis, and embolic nodules. Certain forms of necrotizing vasculitis such as the nodular dermal allergid and allergic granulomatosis should be included here also.

Classic Nodular Lesions of the Legs

Erythema Nodosum

This disorder is characterized by the *sudden appearance of tender, erythematous nodules which are raised slightly above the level of the skin*. They vary from 1 to 5 cm. in diameter and usually favor the shins, although they may occur elsewhere. The lesions are few, are all almost the same age, undergo a series of color changes, and leave no scars. They undergo involution without ulceration usually within a few weeks, although occasionally they persist longer.

The *histologic changes* are located chiefly in the upper part of the subcutaneous tissue while

the cutis merely shows a moderate amount of perivascular infiltrate composed predominantly of lymphocytes. In early lesions there is a scattered infiltrate in the upper part of the subcutaneous fat, which is composed mainly of neutrophils and lymphocytes. Histiocytes and eosinophils are usually present, but plasma cells are absent. As a rule the infiltrate is not heavy and is divided into numerous scattered globules among the fat cells. Abscess formation and necrosis are absent. In some instances the blood vessels are severely involved, while in others there is little or no pathologic change. Epithelioid and giant cells are usually absent in early lesions. Occasionally they are small foci composed of histiocytes lying in palisade arrangement around a small central fissure. These may be permeated by neutrophils, and since they are found in no other disease they are diagnostically important. In old lesions, giant cells, usually of the foreign body type, may occur within clusters of epithelioid cells. Caseation, however, is absent.

Erythema Induratum

Most patients with erythema induratum (necrotic nodular tuberculid or tuberculosis cutis indurativa) have a so-called chilblain type of circulation. The eruption occurs most frequently on the calves of women. *The early lesions are deep-*

seated, subcutaneous infiltrations which extend gradually to the surface, forming bluish-red plaques which ulcerate frequently. Most cases react hyperergically to tuberculin, although a few show reduced sensitivity. The presence of tubercle bacilli has been demonstrated in his-

Fig. 1 — Erythema nodosum. Acute, tender, erythematous nodules on the shins.

Fig. 2 — Erythema induratum. Deep-seated subcutaneous infiltrations usually on the calves of women.

tologic sections and by inoculation of guinea pigs. In many patients, however, no evidence of tuberculosis can be found.

In the deeper portion of the cutis and in the subcutaneous fat there is tuberculoid infiltrate. When the process in the subcutis is diffuse, the term fat-replacing infiltrate may be used. *Collections of lymphocytes, epithelioid cells, and giant cells form chiefly about the blood vessels, the layers of which are greatly thickened (endophlebitis and endarteritis).* There are nonspecific inflammatory changes in the upper portion of the cutis. The elastic and collagenous tissues are absent in the infiltrated zones.

Nodular Vasculitis

In his discussion of inflammatory lesions of the lower leg, Michelson (1952)² stated that the term was applied to both acute and chronic nodular lesions of the lower leg, which may simulate either erythema nodosum or erythema induratum, but diverge sufficiently to exclude diagnosis of either of those diseases. *The disorder is associated with some vascular disturbance, most commonly stasis.*

Histologically there is involvement of arterioles, venules, and larger vessels, especially the medium sized veins, by a granulomatous infiltrate which may extend to perivascular areas. It contains epithelioid cells, plasma cells, and foreign body giant cells, but there is no formation of tubercles. The subcutaneous tissue may be fibrotic or necrotic.

Weber-Christian Disease

The Weber-Christian syndrome was first described by Pfeifer (1892)³ and later by Gilchrist and Ketron (1916).⁴ Weber (1925),⁵ who reported the third case, created the term "relapsing nonsuppurative nodular panniculitis." Subsequently, Christian (1928)⁶ added the adjective "febrile." Clinically the disorder is characterized by the recurrent appearance of subcutaneous nodules located most commonly on the thighs and legs, but occasionally on the arms and trunk. *The lesions coalesce often to form large indurated areas.* As a rule the overlying skin shows no involvement other than mild erythema. Some-

Fig. 3 — Nodular vasculitis. Acute or chronic lesions usually associated with stasis.

Fig. 4 — Weber-Christian disease. Indurated nodules and plaques on the thighs and legs usually associated with malaise and fever.

times, however, the nodules soften and an oily liquid is discharged. Malaise and fever may herald the appearance of new lesions. After the nodules have undergone involution there may be depression of the overlying skin. Hepatomegaly and splenomegaly have been reported. Involvement of the bone marrow may result in anemia, leukopenia, and thrombocytopenia.* Fatal cases have been reported.

In this disorder as in other forms of panniculitis, disturbances of the fat are dependent on alterations of the supplying blood vessels. The small ones are usually dilated and engorged with red blood cells. Their walls may be edematous, thickened, and homogenized. In some cases, larger subcutaneous vessels show mild involvement. These changes lead to focal degeneration of fat cells and hence to outright adiponecrosis. *The necrotic foci are surrounded by a globular inflammatory infiltrate composed of neutrophils, lymphocytes, and histiocytes.* This constitutes the early (acute inflammatory) stage. In the second (lipophagic) phase there is granulomatous formation and imbibition of fat by histiocytes with foamy cytoplasm (macrophages) which dominate the infiltrate. Giant cells and eosinophils may be seen also. In the third and final (fibroblastic) stage there is swelling and homogenization of the connective tissue fibers. Fibrotic replacement of the fat finally results.

Lipogranulomatosis (Rothmann-Makai)

Lipogranulomatosis subcutanea is the term which was used by Makai (1928)⁷ to connote a form of circumscribed panniculitis, although Rothmann⁸ had described the disorder previously (1894). *It is characterized by spherical subcutaneous nodules, the size of which was described vaguely in the older literature as lentil to hazelnut, pea to cherry, and millet seed to walnut.* They average about 12 in number and are most frequently located on the lower extremities, sometimes on the trunk and occasionally on the arms. Their consistency is firm or elastic, and the overlying skin may be hyperemic or normal. Pressure elicits tenderness. The usual duration is six to 12 months, although the disorder has lasted for several years in a few instances. The nodules may disappear within a few days to a few weeks without leaving a trace. Rarely, they break

through the skin and discharge an oily fluid leaving atrophic depressions after healing occurs. Although lipogranulomatosis subcutanea is usually a disease of children, cases have occurred in middle-aged adults. Both males and females are affected. The lack of systemic symptoms, especially fever, and the fact that the lesions do not appear in crops characterize lipogranulomatosis subcutanea. These features are prominent in the Weber-Christian syndrome. The *histologic* pictures of lipogranulomatosis subcutanea and the Weber-Christian syndrome are so similar that differentiation is usually impossible.

Pernio

This disorder is characterized by erythematous nodular lesions occurring on the lower extremities as a response to cold. Female adolescents or young adults are affected most frequently. *The nodules are bluish-red and elevated, and there may be superficial ulceration.* Fifteen to 20 lesions may be present at one time and are usually located just above the ankles. Scars and hyperpigmentation occur after the nodules have healed. The course is long and progressive. The disorder occurs usually during the winter and tends to clear as warm weather approaches.

The *histopathologic features* are nondiagnostic. There may be intimal proliferation, thickening of arteriolar walls, a perivascular infiltration of lymphocytes, neutrophils, and occasional giant cells. A moderate degree of adiponecrosis is sometimes present, although there is no formation of tubercles.

Superficial Thrombophlebitis

This term implies that inflammation is associated with occlusion of a vein by a thrombus. Phlebitis, which is characterized by inflammation of the vessel wall, is not necessarily associated with the formation of a thrombus. The clinical picture depends upon the depth and size of the veins which are affected. The lower extremities are most commonly involved. *When the superficial veins are affected there are tender, erythematous, elevated nodules beneath the skin or cordlike lesions which follow the course of the vessel.* In these cases constitutional symptoms are mild or absent. There is a type of recurrent idiopathic thrombophlebitis (thrombophlebitis

*See Test Your Word Score Page 1097.

migrans) which affects males more frequently than females. In this disorder the small or medium sized veins are involved and there are multiple discrete, tender nodules which involve the legs but may be present anywhere on the body, including the abdomen. The lesions persist for one or two weeks and tend to occur in crops. As a rule the nodules are smaller than those of erythema nodosum or erythema induratum and there is no necrosis or ulceration.

Histologically there is segmental involvement of the affected vein with inflammatory changes of the walls. There may be intense proliferation of the endothelium and partial or complete occlusion of the lumen by a thrombus which contains many fibroblasts. As healing occurs the involved portion of the vein becomes fibrotic.

Periarteritis Nodosa

This disorder is characterized by kaleidoscopic polymorphism, and even though it has been known for almost a century the cause remains a mystery. A definite diagnosis is rarely made until the time of postmortem examination. The classic picture consists of a multiple-organ symptom complex with foci in the heart, kidneys, liver, intestines, muscles, brain, and sometimes the skin. The course is acute or intermittent; sometimes there are angina and arthritis in various joints. The outcome is usually fatal. In contrast to this extremely severe disease with a poor prognosis there are a few cases in which the skin has been involved exclusively. This type has a relatively benign course and may last for several years; there may be non-specific maculopapular, urticarial, or purpuric eruptions as well as those which simulate erythema nodosum or erythema multiforme. *The most characteristic cutaneous lesions of periarteritis nodosa are crops of subcutaneous nodules, especially on the extremities, although there may be livedo racemosa or multiple symmetrical gangrenous lesions.*

Most observers believe that a histologic diagnosis is possible. There is necrosis of the adventitia and media of the medium-sized arteries plus thrombosis and disruption of the elastic tissue of the vessels. There are degenerative and infiltrative changes in and surrounding the affected arteries which are located usually deep in the cutis. *The infiltrate is of a granulomatous type*

with numerous neutrophils and occasional eosinophils.

Relatively New Nodular Lesions of the Legs

Nodular Fat Necrosis with Pancreatic Diseases

Szymanski and Bluefarb (1961)⁹ called attention to this disorder. They observed five acutely ill patients who had cutaneous nodules having a characteristic fat necrosis unlike that present in any disease involving the subcutaneous adipose tissue. In all, disorder was due to disease of the pancreas. In two of the cases the cutaneous nodules preceded the appearance of abdominal symptoms. Four of the patients had acute hemorrhagic pancreatitis and one had adenocarcinoma. *There were raised erythematous cutaneous nodules which were 1 to 2 cm. in diameter (although one had "silver dollar"-sized lesions) which usually appeared on the lower extremities. The lesions were multiple but seldom reached 30 in*

Fig. 5 — Cutaneous periarteritis nodosa. The most common lesions are subcutaneous nodules and symmetrical cutaneous gangrene.

number. They were not clinically characteristic or diagnostic and simulated erythema nodosum, allergic vasculitis, or a drug reaction.

The essential *histologic changes* occurred in the subcutis without involvement of the epidermis or dermis. Foci of fat necrosis were characterized by "ghost-like" cells having thick

"shadowy" walls and no nuclei. Granular material which appeared basophilic was interpreted as dystrophic calcification. There was an inflammatory zone surrounding the foci of necrosis which consisted of neutrophils, eosinophils, lymphocytes, histiocytes, foam cells, and foreign body giant cells. The authors thought that these

Fig. 6 — Necrobiosis granulomatosis. Sclerotic glazed plaques usually on lower portions of the legs.

Fig. 7 — Necrobiosis granulomatosis. Tuberculoid structure in the cutis with multiple giant cells.

features were unique and pathognomonic of pancreatic disease.

Subacute Nodular Migratory Panniculitis

This disorder was described first by Vilanova and Aguade (1956),¹⁰ and more recently by Perry and Winkelmann (1964)¹¹ who reported 14 cases. Subacute nodular migratory panniculitis is characterized by discrete nodules usually on the anterolateral aspect of the legs. In the cases of Perry and Winkelmann, the disease usually started with one nodule which enlarged rapidly in one to three weeks to a diameter of 10 to 20 cm. *The progressive border of the lesion was brightly erythematous, whereas the resolving portion presented a yellowish hue.* As a rule only one leg was affected at first and pain was characteristically absent. As the lesion enlarged, it became indurated and firm and at times was almost sclerodermoid with a mottled consistency. Once fully developed the plaques persisted for periods ranging from months to three years. Most of the patients were females.

Histologically the changes were limited to the septa between the lobules of fat. Numerous histiocytes with the formation of giant cells were seen with massed aggregates up to a dozen or more between any two lobules. There was an associated mild inflammatory reaction characterized by a predominance of lymphocytes, although an occasional plasma cell was seen. There were no eosinophils. Sometimes there was extension into the lobules of fat or the adjacent dermis.

Necrobiosis Granulomatosis

Muller and Winkelmann (1966)¹² believed that this disorder was identical to granulomatosis disciformis chronica et progressiva, a disease which was described by Miescher and Leder (1948).¹³ It is similar to necrobiosis lipoidica diabetorum but differs from it by the apparent absence of diabetes and by the presence of a distinctive tuberculoid infiltrate in the dermis. Diabetes mellitus may develop later, however. *The lesions are round, sharply defined, sclerotic plaques with a glazed-porcelain sheen.* Large lesions are more irregularly shaped and oblong, and the borders are sometimes slightly elevated. The colors of the affected skin are characteristic: in early lesions there are hues of red and brown, but yellowish areas usually develop, especially

near the center of the lesions, as the disease progresses. Violaceous tints are sometimes seen at the periphery of the plaques. The lower part of the leg and ankle, particularly the pretibial area, is the most common location.

Histologically, tuberculoid structure predominates, contrasting to the findings in necrobiosis lipoidica diabetorum where there is extensive necrobiosis and significant amounts of lipid with relatively little epithelioid cell response. Exceptions have been noted however.

Embolic Nodules

Winkelmann (1964)¹ discussed this disorder. Two forms of emboli occur in the skin and may present as inflammatory nodules. In one form the emboli are from a left atrial myxoma; in the other they are from arteriosclerotic plaques. The principal source of emboli from the heart, the mural thrombus, does not produce cutaneous symptoms; but apparently an embolus from this source is so large that it blocks only larger vessels and does not reach the smaller cutaneous ones to produce changes in the skin. Winkelmann stated that single or multiple nodules may occur on the legs. His patient had pain in both calves followed

Fig. 8 — Necrotizing vasculitis. Subcutaneous nodules and purpura.

by the appearance of erythematous nodular lesions on the posterior surfaces of both thighs.

He stated that the results of the laboratory examination were normal in his patient, and review of *histologic sections* was reported to indicate vasculitis. The patient later had a new recurrence of nodular ulcerative lesions of the extremities with a febrile response. Necropsy one year later showed myxoma of the left atrium. On review of all tissue sections it was apparent that the patient had embolization to cutaneous and peripheral vessels which had produced inflammatory cutaneous lesions.

Necrotizing Vasculitis

There are several diseases which vary greatly as far as their clinical features are concerned, but which have in common the microscopic features of inflammation of the arteries in various organs, leading to hemorrhage followed by necrosis. If the arteries and capillaries are affected there may be cutaneous eruptions without interference of the general health. This is the case in the nodular dermal allergid. In the event the medium-sized arteries are involved, the term cutaneous periarteritis nodosa has been applied. If the arteries in organs other than the skin are affected, various syndromes have been described, including allergic granulomatosis, Wegner's granulomatosis, and temporal arteritis.

As the name nodular dermal allergid indicates,¹⁴ the most important lesions are round nodules from 2 to 7 mm. in diameter, some of which are almost at the level of the surrounding skin, while others project from the surface. *The lesions are indurated and well defined without any edema in the environs.* Their color may be that of normal skin, although they are usually red or purple. Besides the nodules there may be purpuric macules from 1 to 5 mm. in size and erythematopapular elements from 2 to 20 mm. in diameter, which are occasionally annular, resembling erythema multiforme. The nodular dermal allergid most frequently affects adults. The lesions occur on all parts of the body, especially on the lower extremities. They have a chronic evolution and absorb extremely slowly, except for the occasional urticarial wheals which may undergo involution in less than 48 hours. The disorder is characterized by remissions and ex-

acerbations; the latter clear within 15 to 60 days, sometimes leaving no trace and other times leaving pock-like scars and pigmentation.

Allergic Granulomatosis

Strauss, Churg, and Zak (1951)¹⁵ described a disorder which they termed allergic granulomatosis, a clinical and pathologic syndrome occurring in individuals with allergic backgrounds. It is characterized by fever, leukocytosis, eosinophilia, and pulmonary infiltrations, accompanied as a rule by manifestations of vascular, cardiac, gastrointestinal, renal, and nervous involvement. *Strauss et al. found that cutaneous lesions were frequent and consisted of erythematous maculopapular eruptions, hemorrhages varying from petechiae to extensive ecchymoses sometimes accompanied by necrosis, and subcutaneous and cutaneous nodules which persisted for weeks or even months.*

Comments

In all types of necrotizing vasculitis, there is swelling of the endothelium of the vessels, the cells of which compress each other and obliterate the lumens in some cases. There is fibrinoid necrosis of the tissue surrounding the vessel which gives rise to a sort of continuous cuff which stains pale pink and looks as though the tissue fibers had been obliterated. There is also an inflammatory infiltrate which not only lies about the area of necrosis but also extends into the surrounding tissues. This infiltrate consists mostly of neutrophils, the nuclei of which are sometimes pyknotic and may be seen lying alone and also with a fine chromatin debris. Eosinophils may be present but are not prominent.

Summary

Several old and relatively new nodular disorders of the legs have been reviewed clinically and histologically. The establishment of a new syndrome must be based on a clearly recognizable clinical pattern, a microscopic picture which is distinctive enough to justify its independence, and a course which is sufficiently characteristic to indicate the usefulness of a new term which implies differences in pathogenesis, prognosis, and treatment. Recognition of these entities thus aids the clinician.

Superior Mesenteric Artery

Occlusion

Successfully

Treated

by

Early

Embolectomy

IN SPITE OF a decade or more of standardized vascular surgical procedures, there have been recorded only eighteen successful superior mesenteric artery embolectomies.^{1-6,9,11-14} This low figure is not too surprising since the lesion is relatively rare, representing less than 0.5% of autopsy material¹ or between 0.02 to 0.015% of all surgical admissions⁷. The proper diagnosis is often not made until the time for successful surgical intervention has passed.

Although the sequelae of sudden superior mesenteric artery occlusion are variable, the majority end fatally without prompt surgical treatment, which requires either restoration of blood flow, resection of involved bowel segments or both. We are, therefore, compelled to make a diagnosis of the condition in its early stages and to proceed with appropriate therapy.

Anatomical Features

To a certain extent the severity of symptoms and the degree of bowel necrosis depend upon the site at which the embolus lodges. In its most common location the embolus is found distal to the origin of the middle colic artery and is also often below the take-off of the first jejunal branch. The proximal small intestine and right colon may, therefore, be nourished, for a period of time at least, via the collateral flow from these vessels, and the amount of infarcted intestine is quite variable. Conversely, if the embolus is proximal to the middle colic artery, the entire right colon and the portions of the transverse colon may be ischemic if marginal arterial collaterals from the inferior mesenteric artery are insufficient.

Clinical Features

The so-called classic history of sudden, severe, diffuse abdominal pain accompanied by nausea and vomiting developing in a patient with cardiac disease, usually atrial fibrillation, is less commonly encountered than a variety of other

BRUCE C. NYDAHL, M.D.**

Minneapolis, Minnesota

*Section of Thoracic & Cardiovascular Surgery, Fairview-Southdale Hospital.

**Section of Medicine, Fairview-Southdale Hospital.

symptom complexes. Physical findings are likewise misleading in many instances, although most patients exhibit generalized abdominal tenderness, moderate distention, and initial hyperperistalsis. As the disease progresses, blood may be passed per rectum indicating mucosal necrosis, and eventually the signs of diffuse peritonitis may occur.

Standard x-ray studies of the abdomen often demonstrate the small bowel to be devoid of gas, apparently due to vigorous initial intestinal peristalsis. Nelson and Eggleston⁸ have described three characteristic x-ray signs of acute mesenteric vascular occlusion including: (1) a

"pseudotumor sign" due to excessive fluid collected in the atonic loops of bowel, (2) an ileus pattern and (3) the "rigid loop sign" due to immobile, edematous loops of bowel. Unfortunately these patterns would seem to represent actual bowel infarction and therefore should not be relied upon to help with an early diagnosis.

Surgical Features

When the diagnosis is suspected, the patient should be prepared for surgery as rapidly as possible. Preoperative hydration and digitalization

Fig. 1 — Electrocardiogram made prior to surgery.

may require a short period of delay and, if this is the case, the patient is heparinized and given antibiotics. Abdominal exploration is best carried out through a midline incision centered on the umbilicus and extended as required. Pains-taking inspection is necessary to determine the exact limits of mesenteric pulsations and ischemia. Since most emboli are lodged at or just below the middle colic branch, exposure is easily obtained by retracting the mesocolon cephalad and dissecting out the branches of the superior mesenteric artery in the root of the mesentery. An alternative approach is through the gastrocolic omentum. A longitudinal arteriotomy placed over the distal extent of the embolus allows its removal in almost all cases. A small balloon arterial catheter passed proximally may facilitate this. Distal emboli and thrombi lodged in the more peripheral arterial arcades are considerably more difficult to remove and may require retrograde flushing and manual compression to be extruded. Fortunately, early thrombotic propagation into the distal arteries is not common. In most cases it is possible to reconstruct the artery with interrupted fine sutures without a patch graft. The small bowel is then inspected, and the decision for definitive resection is made. Frankly necrotic bowel must be resected, but frequently areas of questionable viability will be encountered, and in such instances it is best to close the wound and re-explore the abdomen twenty-four hours later. However, as Rutledge⁹ has pointed out, in none of the reported cases of successful embolectomy have such "second look" operations disclosed bowel requiring resection. Immediate postoperative heparinization is probably not necessary if adequate flow has been established and may cause considerable intraperitoneal bleeding or hemorrhage from ischemic areas of bowel mucosa. However, anti-coagulation should be resumed in all patients with cardiac problems in the early postoperative period.

The following case report illustrates many of the features pertinent to the diagnosis and treatment of superior mesenteric artery embolism.

Case Report

A 77-year-old Caucasian male was admitted to Fairview-Southdale Hospital June 12, 1966, with the history of generalized abdominal pain associated with nausea and vomiting of ten hours' duration. The pain was more

intense in the periumbilical area and was constant. The patient had recently been discharged from the hospital because of generalized cardiac decompensation. At the time of his first admission, he had pulmonary and peripheral edema, pleural effusions, cardiomegaly, and an irregular rhythm. The electrocardiogram showed atrial fibrillation with rapid rate (120), numerous multifocal premature ventricular contractions, and an intraventricular conduction defect. He was digitalized and treated with a low-sodium diet, diuretics and Pronestyl. On this regimen he improved.

Physical Findings

Pertinent physical findings on the second admission showed the chest to be clear to percussion and auscultation. The heart rate was 70, the rhythm was irregular and many extrasystoles were present. No murmur was heard. The point of maximum intensity was halfway between the midclavicular line and the anterior axillary line in the fifth intercostal space. The abdomen was soft and undistended. Bowel sounds were present and normal in quality. There was tenderness in the periumbilical area on palpation with bilateral guarding. Rebound tenderness was absent, and there were no palpable masses. Rectal examination was negative. The peripheral pulses were all intact, and there was no edema.

Laboratory Studies

The white blood count was 19,500, with 83% neutrophils and 17% lymphocytes. The hemoglobin was 15.3 Gm.%. A urinalysis showed a trace of albumin and one

Fig. 2 — Abdominal flat plate illustrating complete absence of all small bowel gas.

plus white blood cells/hpf. Two-hour urine amylase was 254 units. Serum electrolytes were within normal limits. The electrocardiogram was essentially unchanged from the previous admission except for more frequent premature ventricular contractions (Figure 1). The chest x-ray showed a slightly enlarged heart, although smaller than on the previous admission. Abdominal films showed a complete absence of small bowel gas (Figure 2).

Fig. 3 — Removal of embolus from superior mesenteric artery.

Fig. 4 — Normal postoperative small bowel mucosal pattern.

Surgical Findings

A diagnosis of acute abdomen, probably on the basis of mesenteric artery embolism or thrombosis, was made and the patient underwent laparotomy. The superior mesenteric artery was found to be pulseless beyond the takeoff of the middle colic artery. The first portion of the jejunum was normal, but two feet beyond the ligament of Treitz there was a dilated, edematous, pale segment of jejunum approximately 12 inches in length which had no peristalsis. The remainder of the small intestine was normal in color and had adequate peristalsis, although no arterial pulsations were present in the mesentery supplying this area. The superior mesenteric artery was opened at the point of occlusion and a well-organized embolus was removed (Figure 3). Following closure of the artery, pulsations were felt at the level of the major arcade in the mesentery, but not in the more distal branches of the jejunum or ileum. The color of the involved segment of bowel improved and active peristalsis returned. The abdomen was closed, and it was decided to re-explore the patient 24 hours later in order to determine if any demarcation of bowel had occurred. On re-exploration, the 12-inch segment of proximal jejunum was slightly boggy, but exhibited peristalsis and a normal color. The remainder of the bowel appeared quite normal except for numerous ecchymotic areas. Following surgery the patient had an uneventful, although prolonged recovery. Upon resumption of a normal diet he had some diarrhea and postprandial periumbilical cramping, which lasted for one month.

Follow-up

At subsequent follow-up examinations the patient has demonstrated no abnormal bowel function. A small bowel x-ray showed a normal mucosal pattern (Figure 4). There is no evidence of any malabsorption or any dietary intolerance. He continues to have atrial fibrillation but is well compensated on digitalis.

Comment

Although the abdominal findings were not dramatically pronounced on initial examination in this particular patient, when considered in the light of recent congestive heart failure and atrial fibrillation, the entire picture suggested acute superior mesenteric artery occlusion. Early exploration and embolectomy allowed restoration of blood flow before actual intestinal infarction developed.

Immediate postoperative heparinization was begun, but this was associated with the presence of considerable intraperitoneal bleeding at the time of re-exploration, presumably from the area of mesenteric dissection, and therefore was discontinued.

After an initial period of nutritional adjust-

ment of about one month, the patient ate normally, and there has been no clinical evidence of malabsorption. Furthermore, the small bowel pattern was noted to be entirely normal. We feel this is fortunate, because several authors have described chronic malabsorption states in patients surviving superior mesenteric artery embolotomy^{10,12}.

Summary and Conclusions

Successful superior mesenteric artery embol-

tomies have been reported infrequently. Constant vigilance is required to select patients with the findings and history suggestive of superior mesenteric artery occlusion and submit them to early abdominal exploration if the sequelae of bowel necrosis are to be avoided. A case history has been included which illustrates certain pertinent diagnostic features and outlines the therapeutic measures which allowed a successful result following early superior mesenteric artery embolotomy.

The Physician's Image In Ancient India

To the sick man the doctor is a father: to the man in health a friend: the sickness passed and health restored, a preserver.

Without practical training and merely by hearing lectures and by the repetition of discourses, a pupil is like an ass with a burden of sandalwood, for he knows its weight but not its value.

He who knows only one branch of his art is like a bird with one wing. . . . He who is versed only in books will be alarmed and confused, like a coward on a battlefield, when confronted with active disease; he who rashly engages in practice without previous study of written science is entitled to no respect from the best of mankind, and merits punishment from the king; but he who combines reading with experience proceeds safely and surely like a chariot on two wheels.

The physician, the patient, the medicine and the nurse are the four feet of medicine upon which the cure depends. When three of these are as they should be, then by their aid the exertions of the fourth, the physician, are of effect, and he can cure a sore disease in a short time. But without the physician the other three are useless. . . . A good physician can cure a patient alone, just as a pilot can steer a boat to land without sailors.*

*The Code of Manu (400 B.C.—200 A.D.)

Your Health—Mr. President!

Zachary Taylor (1784-1850)

A Bowl of Cherries

Did our twelfth president, Zachary Taylor, die of overeating on cherries?

Throughout childhood and youth Zachary was healthy and hardy; not until military service in the Indian and Mexican Wars was his constitutional integrity violated and perhaps permanently impaired by the acute intestinal infection so perniciously endemic to the appallingly unsanitary army camps of that era. Of his second febrile attack with dysentery he said: "The fever confined me to my bed for near two weeks, when so many was dying around me who I could render no service nor even pay a friendly visit. . . But after taking a large quantity of active medicine principally calomel, and living altogether on hot drinks the disease was subdued, but left me very much debilitated."

Though needlessly rash and reckless throughout his military campaigns Taylor was on the receiving end of bullets only once. From one of his biographies we learn: "One ball passed through his left sleeve above the elbow in the part between the arm and the body, making a large hole where it went in and where it came out. . . It cut through both of his shirts and grazed the skin of his arm. Another entered the breast of his coat, cut through the lining for several inches, and came out at the button hole, tearing it away."

During Taylor's occupancy of the White House his otherwise personable appearance was somewhat marred by undue obesity; for his height of five feet eight inches he weighed 200 pounds. Rather striking also was a strabismus, that impelled him to keep one eye partially shut while in close conversational proximity to anyone.

At an Independence Day celebration in 1850, after Taylor had stood and walked under a blazing sun too long, he became overheated and inordinately thirsty; whereupon he drank vast amounts of ice-cold water, then ate huge quantities of cherries, finishing off his binge with more ice-cold water and milk. As if that were not more than sufficient he topped off his dinner that same evening with more ice-cold water and more fruit, principally cherries, even at the protest of his doctor who was present at the meal. The inevitable result: severe cramps and diarrhea that abated temporarily and slightly—only to resume more violently with vomiting of watery bile and then demise. Standing helpless and defeated at the bedside the several attending physicians debated the cause of death with no consensus; and no autopsy was conducted to establish which of the dissenting opinions presented the correct diagnosis of Taylor's fatal disease.

However, the myth promptly disseminated, gaining momentum and credence, that Zachary Taylor's death was due to overconsumption of cherries: a prime example of how the post-hoc-ergo-propter-hoc fallacy can generate an irrefutable national legend.*

Editor's Note: With unrelenting vomiting and diarrhea the modern doctor would no doubt have made a diagnosis of massive water loss and an electrolyte imbalance as a contributory cause of death.

Solitary Myeloma of Bone

Report of a Case 13 Years After Diagnosis

PABLO RAMOS, M.D.*
P. L. JOHNSON, M.D.*
R. R. KLING, M.D.*
Bismarck, North Dakota

SOLITARY MYELOMA of bone, or plasmacytoma,** is extremely rare. When diagnosed as such, it is frequently only the precursor of generalized myeloma. True solitary myeloma, if properly treated, follows a benign course and has a good prognosis. We agree with Carson and associates³ that if the so-called solitary lesion is followed long enough, it will show evidence of generalization, while the true solitary myeloma is rare. In 1941, Willis¹⁴ reported only 13 genuine cases in a review of the literature. By 1964, Cohen *et al.*⁵ had added 13 more cases which met the criteria of the true solitary lesion.

We wish to report a case in which, although the lesion was diagnosed in 1952, the tumor had apparently begun its course in 1951.

Case History

A 43-year-old white man was first seen in May, 1952. In January, 1951, he had strained his back by lifting a motor. This had resulted in mild low-back distress until March, 1951, when he noticed pain extending down the left leg along the posterolateral aspect to the ankle. Coughing and sneezing aggravated this pain. About six months later he consulted a chiropractor and received multiple manipulations, with apparent relief of pain, although he had been unable to work during the period of treatment.

He had also sustained a severe back injury in 1931, which resulted in a compression fracture of D-8, from which he had recovered.

Physical Findings.

He walked with a stiff, guarded, forward-leaning gait. His spine was rigid and straight and the low-back motion was about 25 per cent of normal. There was a 4.5 cm. atrophy of the left thigh, although the calves were symmetrical. There were no other physical abnormalities noted.

X-ray Findings

Roentgenograms of the lumbar part of the spinal column showed a large osteolytic lesion involving L-3 (Figure 1). The process extended mostly over the right side of the vertebral body and posteriorly, with destruction of the right pedicle and expansion of the most medial portion of the right transverse process. The

*Quain & Ramstad Clinic, Bismarck, North Dakota.

**See Test Your Word Score Page 1097.

lamina and the anterior portion of the spinous process were also involved. Its appearance was that of a mixture of an expanding and cystic lesion showing some trabeculation. The roentgenograms were interpreted as indicating a growth that was probably primary; but a metastatic lesion could not be ruled out.

Films taken elsewhere in 1931 and in September, 1951, (Figure 2) were examined. No lesion was present in 1931, although there was evidence of pathologic changes in the 1951 films, which showed a definite osteolytic lesion in the right side of L-3. The lesion had grown considerably since that date.

Roentgenologic survey of the rest of the skeleton was negative.

Laboratory Findings

Laboratory studies included hemoglobin, red and white-blood cell count, urinalysis and sedimentation rate. All were normal. Within a month after this first examination, needle biopsy was attempted without success. This was followed by laminectomy and removal of all the grossly visible tumor.

The tissue was comprised of sheets of densely packed plasma cells, quite regular and mature in type (Figure 3). The histologic diagnosis was myeloma.

Postoperative Course

The patient did well postoperatively and received a

full course of radiation therapy. He has been seen periodically in our clinic since.

In January, 1953, he reported some discomfort in the wound area. Roentgenograms showed the surgical defect without any definite evidence of bone regeneration (Figure 4). In December, 1958, he denied any distress and was working without difficulty. He had an excellent range of back motion with no apparent guarding. Roentgenograms of the chest and spine revealed no evidence of any new lesion. In October, 1964, he was still symptom-free. Laboratory studies showed a total serum protein of 8.1 Gm. per 100 ml., with albumin 5.5 Gm. and globulin 2.6 Gm.; serum calcium was 11.5 mg. per 100 ml. Serum electrophoresis showed a normal pattern; bone-marrow examination revealed no evidence of dyscrasia.

The patient was last seen in October, 1965, at which time roentgenograms showed bone regeneration of L-3 without evidence of any active lesion. (Figure 5). The patient denied any pain referable to the involved area.

Comment

Although the lesion in our patient was not diagnosed definitively until May, 1952, roentgenograms in September, 1951 (Figure 2), indicate the lesion was then apparent. The patient can

Fig. 1—Obvious involvement of the right side of vertebral body, including lamina and transverse process.

Fig. 4—Roentgenogram 6 months postoperatively and postirradiation shows no definite bone regeneration.

thus be said to be alive and well more than 14 years after his first symptoms appeared.

Some disagreement exists in the literature regarding this entity. Since some long-term solitary lesions eventually generalize, some question occurs whether all solitary lesions are precursors of multiple myeloma.

Bichel and Kirketerp,² and Christopherson and Miller⁴ believed that a three-year survival rate was sufficient to justify the diagnosis; but many lesions have disseminated after three years. Raven and Willis¹¹ stated that a one-year follow-up with negative roentgenologic findings should be ample. Pasternack and Waugh¹⁰ reserved the term "true" solitary myeloma for lesions showing no recurrence or secondary foci for four to 10 years after diagnosis.

In our case only one bone-marrow examination was made, although some authors believe serial bone aspirations should be done. However, Lichtenstein and Jaffe⁹ found that negative bone marrows and even a negative autopsy report might not rule out other foci of myeloma. We believe that such examination done this late in

our post-diagnosis period would help considerably to corroborate or disprove the original diagnosis. While we agree with Bichel and Kirketerp² that bone-marrow studies are important in diagnosing this condition, we also find a case reported by Baitz and Kyle¹ in which myeloma developed after a 40-year history of osteomyelitis; bone-marrow examinations, among other tests, were negative despite the rapid generalization of the disease which preceded the death of the patient.

One skeletal survey was made on our patient; this was immediately preoperative. The variability of skeletal spreading either locally or generalized is well seen in one of the cases reported by Kaye *et al.*⁸ in which skeletal invasion was evident 12 years after the lesion was first diagnosed. Skeletal invasion produces symptoms more often than not, and since our patient has been symptom-free since at least 1958, no such study has been done except for thoracic roentgenograms at each visit. Three years postoperatively, skull roentgenograms were negative.

The two most interesting facets of such tumors are their rarity and the different approaches to the

Fig. 5—Roentgenogram 13 years postoperative and postirradiation shows bone regeneration without evidence of recurrence.

subject in the literature. If there exists a true "solitary" benign lesion without evidence of generalization, the number of reported cases is extremely small. Carson and co-workers,³ in reviewing 90 cases, accepted this rarity as an entity but stated that, given a long enough time, most of the patients will show diffuse plasma-cell myeloma. As recently as 1964, Cohen *et al.*⁵ reported on a patient in whom disseminated myeloma developed 21 years after the original "benign" lesion had been excised.

The approaches to the subject vary considerably in the literature. Our patient was not tested for Bence Jones proteinuria. Cohen *et al.*⁵ demonstrated that the presence of this protein in the urine does not necessarily imply brief survival. One of their patients who had a normal bone marrow at the time of the original diagnosis also had Bence Jones proteinuria but survived for 10 years. Interestingly, he died of local extension of a sacral myeloma without evidence of generalization at autopsy.

Weiner,¹³ in reviewing 60 cases, studied serum-protein changes by electrophoresis and found that these, as well as Bence Jones proteinuria, were seen only occasionally in plasmacytoma of bone. The serum electrophoretic pattern in our patient was normal.

The relationship between multiple myeloma and the true plasmacytoma remains only partially answered. Christopher and Miller⁴ stated emphatically that there was no relationship. Johnson and Meader⁷ reported a case with two different foci of myeloma with identical microscopic characteristics, indicating the possibility that the tumor was multicentric and yet benign. Their patient was alive six years after discovery of the lesions. They suggested the possible distinction between the two entities, defining the so-called solitary myeloma as nothing more than reactive hyperplasia of the marrow involving the cytoplasmic characteristics of the histiocytes;^{*} this would serve to make the differentiation from true

myeloma, either solitary or multiple. However, they admitted the possibility that this hyperplasia may undergo sarcomatous changes and that predictions as to behavior of benign solitary myelomas should be made cautiously.

Ritz and Meyer¹² also agreed that the relationship between solitary and multiple myeloma should be clarified. They suggested the term "plasmacytoma" be used for those lesions in which the outcome is in doubt, reserving the terms "benign" or "malignant" plasmacytoma for those with distinct characteristics. They did not, however, elaborate on the length of time which should elapse before determination of the benignancy.

The same spectrum of approaches is apparent in the various roentgenograms offered for examination. While Jacobson *et al.*⁶ considered destruction of the pedicle as characteristic of metastatic carcinoma or a very late sign in myeloma, Cohen and co-workers⁵ found pedicle destruction in 20 of their 55 cases of isolated vertebral myelomas.

Conclusions

While most of the lesions described are osteolytic, roentgenographic diagnoses of metastatic and giant-cell tumors, aneurysmal bone cyst and Ewing's sarcoma have been made in an attempt to offer prognostic help. This attempt has not been particularly rewarding and we feel, as many do, that differential diagnosis is not possible without biopsy or other supplementary studies or both.

One point of common agreement emerges: treatment of these lesions is biopsy followed by well-conducted radiation therapy. All factors being equal, this approach should bring about a benign course and a good prognosis.

Upon review of the literature and comparison of the symptomatology, definitive diagnosis, post-operative course and 14-year survival record, we believe our case to be that of a benign solitary myeloma.

The Minnesota State Bird*

A few years ago, after much debate, the common loon was named the Minnesota state bird. To many the loon meant only a bird with a weird cry which had given rise to such expressions as "crazy as a loon." However, to many dedicated lovers of wild life the loon represents a true symbol of the wilderness. Dr. W. J. Breckenridge, Dean of Minnesota Wild Life Students and Teachers, has been quoted in part as saying, "The loon expresses the essence of unrestrained wildness and seems to put the stamp of genuineness on a north country setting."

Last May during three days of bass fishing in a sheltered bay of Long Lake near Park Rapids, my fishing partner, Paul Wilson, and I made the acquaintance of the nesting loon of this cover picture. At first she would leave the nest when we were 50 to 75 yards away, making wild and angry cries, and further tried to distract us by rearing up on her tail and throwing out her chest with a great flapping of wings. As we drifted on fishing, she would slowly return and with awkward waddling resume her place on the nest. It is amazing that one of the world's greatest swimmers can be so helpless on land. After several fishing trips she finally decided to accept or ignore us.

On a particularly beautiful morning as Paul worked the boat toward the nest, I took pictures at various distances without disturbing Mrs. Loon. The picture presented was taken as a 35-mm. slide at a distance of twelve feet on Kodachrome II using a 135 mm. lens.

Medical Men on Postage Stamps

Rene Laennec (1781-1826) was a French physician, author of a book on chest diseases, and inventor of the stethoscope. A one-foot-long wooden cylinder constituted Laennec's first crude instrument for auscultation; with it he listened to mysterious chest wheezes, rattles, and whistles which at the time confounded him but which he later was able through autopsies to correlate with the disorders that had produced them. In 1952 France acknowledged its debt to him by issuing a postage stamp in his honor.

Federico Roldan (1864-1942) was a Cuban physician who introduced radiotherapy and physiotherapy to his native country. In commemoration Cuba issued a postage stamp honoring him in 1958.

Ancient Greeks in Medicine*

ARETAEUS (1st century A.D.) described asthma, tetanus, epilepsy, diphtheria, hysteria, satyriasis, warned against excess of bloodletting, seems to have understood the direction of the blood-flow in the veins, and was the author of the first systematic account of diabetes.

ASCLEPIADES (1st century B.C.) was the first who definitely divided disease into acute and chronic; he described malaria, catalepsy, frenzy and lethargy, and treated the insane with gentleness, sunlight, music and song.

HELIODORUS (3rd century A.D.) wrote on operative treatment of hernia, stricture, resections, flap and circular amputations, bandaging, probing injuries to the skull and torsion of blood vessels.

SORANUS (98-138 A.D.) stands out as the first specialist in diseases of women and children.**

Thrombocytopenic Purpura and Intra-Uterine Growth Retardation

*of
the
Newborn
Following
Maternal
Rubella*

HENRY P. STAUB, M.D.
Minneapolis, Minnesota

RECENT PAPERS have reported purpura, thrombocytopenia, intra-uterine growth retardation, hepatosplenomegaly, bone changes, and other anomalies as new features of the rubella syndrome.^{1,2,3,4} The question arises whether these are new manifestations due to a change in pathogenicity of the virus or whether these features may previously have been missed. This report of three cases from the years 1958 and 1959 demonstrates that such complications occurred prior to the recent epidemic.

Case Reports

Case 1

A 23-year-old mother was seen by her family physician during the sixth week of pregnancy and was diagnosed to have German measles. The pregnancy was otherwise uncomplicated. Her last menstrual period had been on 4.27.57, the date of expected confinement was 2.2.58, and the birth occurred on 1.16.58 at 38 weeks of gestation. Delivery was normal. Physical examination revealed a 3 lb., 14 oz. boy; length 17½ inches, head circumference 12 inches, chest circumference 11½ inches. Reddish-blue hemorrhagic macular areas from pinpoint size to 3 to 4 mm. in diameter were present over the entire body. They did not fade on pressure and were typically purpuric. No new lesions appeared and by the twelfth day the lesions had almost completely faded. At two weeks of age a short, rough systolic murmur had developed which gradually became louder. A presumptive diagnosis of interventricular septal defect was made. The murmur later disappeared. At the age of four weeks the baby developed coarse tremors which persisted for several weeks. When he was two months old, cloudiness of the cornea of both eyes was noted and a diagnosis of congenital glaucoma was made. Goniotomies were performed on both eyes in May and December 1958. Cataract developed in the right eye; good vision (20/50) was achieved in the left eye.

Repeated platelet counts showed significant reduction: at the age of 24 hours the count was 77,000/ml³, at the age of four days 40,000/ml³, at six weeks 149,000/ml³, at two months 138,000/ml³, at four months 133,000/ml³, and at five months 160,000/ml³.

An interval history was obtained when we had an opportunity to see him again in December 1964 at age 6 11/12 years. Psychometric testing in January 1960 on the Cottrel Infant Scale had shown a chronological age of two, a mental age of two, an I.Q. of 100; and on 6.20.62 a Stanford-Binet I.Q. was 109+. In July 1963 he had bilateral heel cord lengthening. In November 1963 he had bilateral tenotomies of the adductor muscles with obturator neurectomy.

Although he spoke slowly with a definite though not severe defect and mispronounced some words, he could be easily understood. He was friendly and cooperative.

Physical examination showed his weight to be 51 pounds, his height 46½ inches, his head circumference 49 cm. The deciduous teeth were short and appeared worn, with yellow discoloration of the enamel. There was no heart murmur. He had severe spasticity of the lower extremities. He walked well with crutches, but when walking alone he moved his legs mainly by stiffening and rotating his hips. Coordination of his hands was good. He attended special school.

Case 2

A 22-year-old nurse had her first successful pregnancy after two miscarriages. Her last menstrual period had been on 3.19.59; her expected date of confinement was 12.22.59.

Rubella was diagnosed on 4.23.59 by her obstetrician and a dermatologist. Pregnancy, labor and delivery were otherwise normal. The patient, a girl, was born on 12.17.59 at 40 weeks of gestation, weighing 4 pounds, 15½ ounces; length 19 inches, head circumference 12½ inches, chest circumference 12 inches. There was a generalized eruption of small macular blue-red spots which did not fade on pressure, characteristic of purpura. The left eye showed microphthalmia and a cataract. There was a grade two apical systolic murmur which had disappeared by the fourth day.

Repeated platelet counts were significant: on the first day of life duplicate counts were 37,000/ml³. and 34,000/ml³.; at one month the platelets had risen to 171,000/ml³. and showed conspicuous pleomorphism with many giant forms; at 4½ months the count was 235,000/ml³. and the platelets were morphologically normal.

During the first year of life the child had frequent upper respiratory infections and recurrent purulent otitis media. In July 1960 and January 1961 dissection of the second pupillary membrane of the microphthalmic left eye was done. Examination of the right eye showed a salt-and-pepper type fundus and a disc-sized area of an old choroiditis just temporal to the right macula.

At five months she weighed 12 lbs., measured 24½ inches with head and chest circumference of 37 cm. each. In April 1965 at the age of six years, she weighed 29 pounds, her measured height was 40¼ inches with head and chest circumferences of 46 cm.

She sat at seven months, took a few steps alone and walked around furniture at 12½ months. She was a bright, pretty, petite little girl, with a normal intelligence when tested with a Stanford-Binet Form LM: at C.A. 5-7 (M. A. 6-2, I.Q. 112). The Binet was corroborated by the Goodenough test and history from the mother.

Hearing tests showed a very slight high frequency sensory hearing loss, so slight that it had no effect on her speech and language behavior. The results of the Peabody Picture vocabulary test indicated language development well in advance of her chronological age.

Case 3

During the second month of suspected pregnancy

a 41-year-old mother contracted what was thought to be rubella. She had a rash, sore eyes, and a fever. She was seen by her family physician who took a "rabbit" test which confirmed the pregnancy. Except for a renal infection during the last trimester the pregnancy was normal. Her last menstrual period had been 1.27.59; her date of expected confinement was 11.4.59. The infant was born at 42 weeks of gestation on 11.17.59 after normal labor and delivery. The placenta showed multiple infarcts. The infant weighed 3 pounds, 1½ ounces; length 16½ inches; head 12¼, chest 8¼ inches. There was a generalized purpuric macular rash. The right testis was not palpable; the left testis was in the inguinal canal. There was a grade 2 systolic apical murmur which disappeared at two weeks. The eyes appeared normal.

Significant laboratory findings were: the platelet count on 12.2.59 was 100,000/ml³.; on 12.16.59 the platelets were markedly pleomorphic with a count of 104,000/ml³., and on 12.28.59 the count was 224,000/ml³.

At discharge when two months old the infant weighed 5 pounds, 4½ ounces. At nine months of age he appeared grossly retarded (weight 13 pounds, 2 ounces, height 68 inches, head 42 cm., chest 37 cm.). His highest level of achievement was to roll over, but he was beginning to imitate sounds and was able to hear. His head was of the long, narrow scaphocephalic type. The fontanel and coronal sutures were open. His back tended to be arched, his fists clenched. He was unable to sit alone but stood with support in a typical six-month pattern with the feet plantar flexed. His deep tendon reflexes were brisk, Babinskis were bilaterally positive, Moro was absent.

At the age of two years he started to walk around furniture. He used his upper extremities and his hands quite well but still arched his back and had marked spasticity in the lower extremities. His measurements were: weight 17½ pounds, height 83 cm., head 45.3 cm., chest 43 cm. At age 3¼ years he weighed 22 pounds, 8 ounces, and measured 36½ inches; but he still did not walk alone. Psychometric testing at C.A. 3.6 showed M.A. 1.9, I. Q. 50 on the Cottrell Infant Intelligence Scale. His hearing was apparently grossly normal. His speech was poor; he had difficulties with coordination, jaw, lip and tongue movement.

Discussion

That the intra-uterine growth retardation in these patients was striking, fits well with Warkany's concept.⁵ The children's birth weights were much less than expected for these gestational ages: 3 pounds, 14 ounces at 38 weeks, 4 pounds, 15 ounces at 40 weeks, and 3 pounds, 1½ ounces at 42 weeks in the three cases. Their head circumferences were also small for their gestational age; but the measurements were near to the expected mean values for the birth weight. None of the children has "caught up" with his normal siblings. However, when last seen one

was near the mean in height and weight, and another had a fairly normal height. Otherwise, height, weight, head circumference were grossly abnormal, generally below the 3rd percentile. Two of the children are spastic; one with severe spasticity is also markedly retarded mentally.

The purpura at birth was striking. In every case it was initially thought to be unrelated to the history of maternal rubella. Two infants had platelet counts checked within 24 hours; these were significantly depressed. The platelets in the third child were not checked until 14 days of age when the count was 100,000/ml.³ and the platelets were markedly pleomorphic.

All three children had loud heart murmurs during the neonatal period, which disappeared early. This might represent closure of a patent ductus or patent atrioventricular canal.

More recently described features of the rubella syndrome were probably missed in our cases. X-rays of the long bones were not taken. There were no notes on the size of the liver or spleen. However, thrombopenic purpura and intra-uterine growth retardation were recognized as features of the syndrome.

The early work with rubella syndrome and its traditional involvement of eyes, ears, heart and teeth was done in older children. The rather transient and harmless purpura, "bruising from birth," could have been easily passed over and forgotten. Only in recent epidemics when the diagnosis of rubella syndrome was made at birth, did the relation of purpura, bone changes, enlarged liver and spleen to the rubella syndrome become obvious. The fact that thrombocytopenic purpura did occur in three newborns in 1958-1959 suggests that the more recently described features of the rubella syndrome were missed in the past and not that the virulence of the virus or the character of the diseases changed.

Summary

Three cases of the rubella syndrome of the newborn with purpura, thrombocytopenia, and intra-uterine growth retardation that occurred in 1958 and 1959 are reported.

The author wishes to express his appreciation to the referring physician of each of the three cases: Calvin Elrod, M.D., Charles A. Friend, M.D., and Joseph I. Hamel, M.D.

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures highlighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Quackery in the Middle Ages

There are so many little arts used by mountebanks and pretenders to physic, that an entire treatise, had I a mind to write one, would not contain them; but their impudence and daring boldness is equal to the guilt and inward conviction they have of tormenting and putting persons to pain in their last hours, for no reason at all.

Now some of them profess to cure the falling-sickness, and thereupon make an issue of the hinder part of the head, in form of a cross, and pretend to take something out of the opening, which they held all the while in their hands. Others give out, that they can draw snakes or lizards out of their patients' noses, which they seem to perform by putting up a pointed iron probe, with which they wound the nostril, until the blood comes: then they draw out the little artificial animal composed of liver, etc.

Some are confident they can take out the white specks in the eye. Before they apply the instrument to that part, they put in a piece of fine rag into the eye. Some again undertake to suck water out of the ear, which they fill with a tube from their mouth, and hold the other end to the ear; and so spurring the water out of their mouths, pretend it came from the ear. Others pretend to get out worms, which grow in the ear, or roots of the teeth. Others can extract frogs from the under part of the tongue; and by lancing make an incision, into which they clap in a frog, and so take it out.

What shall I say of bones inserted into wounds and ulcers, which, after remaining there for some time, they take out again? Some, when they have taken out a stone from the bladder, persuade their patients, that still there's another left; they do this for this reason, to have it believed, that they have taken out another. Sometimes they probe the bladder, being altogether ignorant and uncertain, whether there be a stone or no. But if they don't find it, they pretend at least to take out one they have in readiness before, and show that to them.

Sometimes they make an incision in the anus for the piles, and by repeating the operation often bring it to a fistula or an ulcer, when there was neither before. Some say they take phlegm, or a substance like unto glass, out of the penis or other part of the body, by the conveyance of a pipe, which they hold with water in their mouths. Some pretend that they can contract and collect all the floating humors of the body to one place by rubbing it with winter cherries; which causes a burning or inflammation; and then they expect to be rewarded, as if they cure the distemper; and after they have supplied the place with oil, the pain presently goes off.

Some make their patients believe they have swallowed glass; so, taking a feather, which they force down the throat, they throw them into a vomiting, which brings up the stuff they themselves had put in with that very feather. Many things of this nature do they get out, which these imposters with great dexterity have put in, tending many times to the endangering the health of their patients, and often ending in the death of them.

Such counterfeits could not pass with discerning men, but that they did not dream of any fallacies, and made no doubt of the skill of those whom they employed; till at last when they suspect, or rather look more narrowly into their operations, the cheat is discovered. Therefore no wise men ought to trust their lives in their hands, nor take any more of their medicines, which have proved so fatal to many.

—Rhazes (850-923)

Idiopathic Hypopara- thyroidism*

Report of a Case

D. P. DANIOLOS, M.D.**
Bismarck, North Dakota

GENERALLY SPEAKING, hypoparathyroidism is an infrequent condition. Particularly since the surgeons have become aware of it as a serious complication following subtotal thyroidectomy, improvements in surgical techniques have lowered the incidence due to injury or accidental removal of the parathyroid gland. Yet even today the majority of cases seen are secondary to surgical trauma.

Idiopathic hypoparathyroidism, however, is an extremely rare primary condition of unknown etiology.

Bronsky *et al.*¹ in 1958 mentioned that in 434,768 patients in Cook County Hospital, there was only one case of idiopathic hypoparathyroidism.

Steinberg and Waldron,² from Queen's General Hospital (New York), reported a case in 1951 and, in reviewing the entire English and foreign literature, were able to accumulate and analyze 52 cases. They emphasized the rarity of this condition, mentioning that in 213,025 admissions to the Queen's General Hospital during a 15-year period, the diagnosis of idiopathic hypoparathyroidism had been established in only one instance.

In 1939 Drake *et al.*³ established the basic criteria for the diagnosis of idiopathic hypoparathyroidism as follows: low serum calcium level; high serum phosphorus level; chronic tetany; absence of x-ray signs of rickets or osteomalacia; absence of renal insufficiency, steatorrhea, chronic diarrhea and alkalosis (conditions which themselves might cause hypocalcemia and tetany).

The etiology of this disease is of course unknown. Only three cases reviewed by Steinberg came to autopsy. In two of them there was no evidence of parathyroid tissue. In the third, all parathyroid parenchyma was found to be completely replaced by fatty tissue.

**Department of Internal Medicine, Quain & Ramstad Clinic, Bismarck, North Dakota.

Case History

Our patient is a male 51 years of age. The case is of unusual interest because the patient had been symptomatic since the age of 14 and untreated up to this time. It is, I believe, the only case reported in the literature to remain symptomatic for 37 years prior to the institution of therapy. A case reported by Steinberg² was symptomatic 31 years prior to diagnosis.

Until the age of 14 this man was a perfectly normal and healthy boy, doing well in school in a small town in South Dakota. At the age of 14 he had his first seizure, diagnosed by a South Dakota physician as grand mal epilepsy. He then had frequent epileptoid seizures described as tonic and clonic convulsions with some foaming from the mouth and tongue biting. During the first year of his illness he was seen and treated repeatedly by several physicians in South Dakota, who all agreed as to the diagnosis of epilepsy. In spite of proper treatment the boy continued having frequent seizures and, in addition, became extremely restless, nervous, and difficult to manage. He was forced to quit school. During this first year of illness he became so disturbed and unmanageable physically as well as mentally and emotionally that he was finally committed to the Jamestown State Hospital where he was treated for approximately two years until he was 16. There he was diagnosed as suffering from epileptic psychosis and mental deterioration.

Following his discharge from the state hospital he was maintained on anti-epileptic medications, but continued having convulsions and showing slow, progressive mental deterioration. He lived with his family on the farm and was able to do a few chores around the place until several years ago when he became entirely unable to function mentally or physically at home. Anti-epileptic medications used throughout the course included phenobarbital, mebaral, dilantin and mysoline.

At the age of 22 his vision started failing and two years later he was able to see nothing with the right eye and only very faintly with the left. At that time a diagnosis of bilateral cataracts was made and a mature cataract was extracted from the right eye. A secondary cataract gradually developed over the right eye which had to be operated upon in 1961. The same year a mature cataract was also dissected from the left eye.

During the last five years this patient has been repeatedly treated at the clinic and in the hospital, mainly because of recurrent severe epileptic seizures and mental retardation.

Physical Findings

In March, 1965, he was admitted to the Bismarck Hospital complaining of severe sore throat, edema of the tongue, and hoarseness of voice. He was treated with various agents for approximately one month with no improvement. A direct laryngoscopy and biopsy were performed which revealed inflammatory laryngitis, nonspecific. The physical examination at that time was essentially unremarkable, except for the local inflammatory changes of the mouth and throat, the residual

Graph 1

Graph 2

IDIOPATHIC HYPOPARATHYROIDISM—DANIOLOS

of the bilateral cataract changes, the evidence of mental retardation, marked irritability and tremor, and a generalized muscular spasticity particularly pronounced over the upper extremities where a typical carpal spasm was noted. A strongly positive Trousseau sign was easily discernible, but Chvostek's sign could not be induced. There was no evidence of hair or skin abnormality, though one of his fingers did show changes suggestive of old mycotic infection.

Laboratory Findings

An electrocardiogram revealed a heart rate of 75, a QT interval of 0.48 seconds and a QTc of 0.5 seconds, a tracing definitely suggestive of hypocalcemia (Graph 1). A serum calcium was reported as 4.5 mg.% with a serum phosphorus of 3.5 mg.%. His voice continued extremely hoarse for several days and he soon developed a typical laryngeal stridor.

A repeat evaluation of the serum calcium was reported as 4 mg.% with a serum phosphorus of 4.6 mg.%. Laboratory studies including BUN, alkaline phosphatase, urinalysis, fasting blood sugar, serum creatinine, wbc. and differential were all within normal limits. Total proteins were 5.8 grams with a normal A/G ratio. Serum sodium and chlorides were normal, but the serum potassium was low, 3.3 mEq/l. A 24-hour urinary secretion of calcium was 6 mg.% with a normal of 100 to 300 mg.%. X-ray studies of the chest, intravenous pyelogram, stom-

ach and colon were all normal except for a hiatus hernia. A bone x-ray survey revealed no abnormalities except for calcification of the area of the basal ganglia of the brain. An electroencephalogram was within normal limits (this was the first electroencephalogram ever obtained on this patient).

Treatment

He was treated with intravenous calcium gluconate and calcium lactate orally, dihydrotachysterol (AT-10) (later substituted for by calciferol), a low phosphorus diet and supportive care. His improvement was striking. The muscular irritability and spasticity were promptly relieved; the laryngeal stridor and the mouth and throat discomfort disappeared. Confusion and mental attitude were markedly improved, and two weeks after the initiation of therapy he was able to carry on an almost normal conversation. His family commented that his improvement was so striking they could hardly believe it. Throughout this period no anti-epileptic medications were used and the patient had no convulsions.

He was discharged on April 27, 1965, on calcium lactate, vitamin D 500,000 units q.i.d. and a low phosphorus diet. On discharge the serum calcium was 10.4 mg.%; serum phosphorus, 5 mg.%; a 24-hour urinary secretion of calcium, 162 mg.% (normal 100 to 300 mg.%) and a 24-hour urinary excretion of phosphorus, 250 mg.% (with a normal of 900 to 1,300 mg.%).

Graph 3

Overtreatment

On May 18, 1965, the patient was re-admitted to the hospital complaining of persistent and severe constipation, not relieved by strong laxatives. There was associated abdominal distress, marked anorexia and fatigue. Examination revealed him to be markedly dehydrated, confused, and difficult to understand because of thickness in his speech. There was poor oral hygiene, considerable redness and congestion of the throat and excessive thick mucous secretion in his mouth and throat. A fecal impaction was present. An electrocardiogram revealed a rate of 80 with a QT of 0.24 and a QTc of 0.25 seconds indicative of hypercalcemia. There were prominent U waves suggestive also of hypopotassemia (Graph 2). The serum calcium on that date was 16.6 mg.% with a serum phosphorus of 3.9 mg.%; a serum potassium was 2.6 mEq/l. It was obvious that he had been overtreated. After hydration 10 days later his serum calcium had declined to 6.8 mg.%, the phosphorus to 6.6 mg.% and the patient was again placed on vitamin D and calcium lactate. Since then he has been followed regularly at the clinic and has been maintained on a smaller dosage of Calciferol and no calcium. Graph 3 indicates the patient's course during the interval of 4/1/65 to 8/1/65 with the values of serum calcium and phosphorus and the therapy used during that interval. Since then he has been extremely well, entirely free of any convulsive seizures. He is able to care for himself, work on the farm regularly, and though he is not yet the brightest man on earth, he is able to do things that he had never previously done. Figures 1 and 2 are "before and after" photographs, indicating the obvious improvement.

Comments

In spite of the rarity of idiopathic hypoparathyroidism, the physician should be on the alert for its existence, since the serious complications that may occur if the disease remains undiagnosed could lead to tragic results and perma-

nent serious mental and physical deficiency as shown in this case. Certainly of interest is the ease with which the wrong diagnosis made 37 years ago could mislead a large number of physicians who periodically examined and treated this patient. The improvement in physical and mental status shown after accurate therapy was established was indeed striking.

Tetany

The most common symptom of idiopathic hypoparathyroidism is tetany which, according to Steinberg and Waldron², occurs in 78% of cases. Convulsions occur in 52% and less frequently gastrointestinal disturbances, psychosis, photophobia, and blepharospasm.⁶ In spite of the low incidence and questionable connection of psychosis to idiopathic hypoparathyroidism, the observation of psychosis by Green and Swanson⁴ in five cases of hypoparathyroidism following thyroidectomy is of interest. The psychosis in all those cases responded favorably to the therapy of hypoparathyroidism.

Physical Change

Cataracts were found in 50% of the 52 cases analyzed by Steinberg and Waldron.² These may occur very early in life. Other less common signs are teeth, skin, nail and hair changes, papilledema, fungus infections, mental retardation and chronic conjunctivitis.

Calcium and Phosphorus Abnormalities

Laboratory findings with the exception of the

Figure 1

Figure 2

*See Test Your Word Score Page 1097.

calcium and phosphorus abnormalities are essentially unremarkable. Cantarow and Trumper⁵ mention that serum P concentration may be normal or elevated. Hypocalcemia is always present. The alkaline phosphatase is generally normal. In our case anemia and hypopotassemia were noted for which we have no clear-cut explanation unless they were related to malnutrition and the chronicity of the patient's illness, particularly since a low potassium level was noted during both the hypocalcemia and the later hypercalcemia state. Of the 52 cases analyzed by Steinberg and Waldron² the cerebrospinal fluid was examined in 15 and found to be abnormal in six cases.

Skeletal Changes

There are usually normal skeletal roentgenographic findings. Skull x-rays, however, did reveal calcification of the basal ganglia in seven of the cases in the Steinberg and Waldron review. (This is interesting since of the seven cases abnormal cerebrospinal fluid was found in one instance, papilledema in two instances and mental retardation in two.) In our case calcification of the basal ganglia was also reported. The electrocardiogram usually reveals a prolonged QT interval.

Therapy

The therapy of idiopathic hypoparathyroidism, rewarding as it is, also involves risks, as clearly indicated in our case. Hypercalcemia with its serious toxic manifestations may easily occur if one is not careful to evaluate with accuracy over prolonged periods of time the amount and type of medication best adapted to the individual case. Dihydrotachysterol (AT-10) may be preferable to initiate therapy, but it is considerably more expensive than vitamin D, and in most instances it is possible to continue therapy with maintenance dosages of vitamin D alone or in combination with calcium. In any case, the patient should be followed closely at regular intervals for the rest of his life.

Summary

We have presented a case of idiopathic hypoparathyroidism manifesting most of the clinical symptoms and signs of the disease, which yet remained undiagnosed for 37 years, the longest symptomatic case ever reported in the literature.

The rarity of this condition was emphasized.

Brief review of the clinical and laboratory findings was given as well as highlights of its therapy.

Knotgrass

Knotgrass heals broken joints and is powerful by urine to expel gravel and stone.—Nicholas Culpepper

Candida Albicans Syndrome

Alopecia, paronychia, localized or widespread skin eruptions, and dwarfing have been described in association with *Candida albicans*, a genus of yeast-like fungi that causes human infection. Schultz first reported three cases in 1935; only a few additional cases have been recorded. As a rule the condition is limited to childhood.

The pathologic features have been strikingly constant. Despite the presence of widespread skin eruptions, no fungi are regularly cultured from the skin. The organisms may be cultured from lesions of oral mucous membranes and from stools.

The relation of the fungus to skeletal growth or dwarfing and to the scalp (in causing alopecia and loss of hair pigment) is not understood; these effects may relate to the presence of the fungus in the gastrointestinal tract. The intestinal infection with *C. albicans* is reported to be controlled by the use of thymol or of other antifungal agents.

Radiology Residents Hold Research Symposium

On Thursday, May 25, 1967, a Residents' Day Research Symposium was held by the Department of Radiology at the University of Minnesota. Eight Medical Fellow Specialists presented papers describing their research projects. Presenting papers on the scientific program and the titles of their papers were as follows:

Dr. James MacGibbon: "Comparison of Bone Scanning Using Strontium ^{87m} with Radiography in the Diagnosis of Bone Lesions"

Dr. Anton Neese: *Primary Lymphedema*

Dr. Stefan Laxdal: *Evaluation of Cesium ¹³¹ in Myocardial Scanning*

Dr. Gail W. Haut: *Single Breath Bronchography*

Dr. David L. Moore: *Study of Pulmonary Radiation Changes in Rabbits Using Radioisotope Techniques*

Dr. Gerald Telander: *Relationship of Tumor-Size to Tumor-Brain Concentration Ratio as Studied in a Brain Phantom with Rectilinear and Scintillation Camera Methods*

Dr. Stephen Kieffer: *Intrathecal Radiogold (Au ¹⁹⁸) in the Treatment of Spinal Axis Neoplasms*

Dr. Gustave Formanek: *Present Standards of Coronary Flow Measurements and Experience Seen on the Xenon ¹³³ Technique*

General Chairman for the program was Dr. Yosh Maruyama.

Deficiency of Glucose-6-Phosphate Dehydrogenase

IN THE PAST few years a plethora of papers has attested to the growing interest in and recognition of enzymatic defects in hemolytic disorders. This is exemplified in the interesting report of such a case by Lerner and Doscherholmen.¹

By far the commonest enzyme defect leading to hemolytic disease is glucose-6-phosphate dehydrogenase deficiency. On the basis of the high gene frequency (about 13%) of glucose-6-phosphate dehydrogenase deficiency among American Negroes alone, it is estimated that about 3,000,000 people in the United States carry genes for this disorder. Thus, this deficiency is second only to blood-group (Rh) incompatibility as a potential cause of hemolytic disease. Recent large surveys indicate that this may be a commoner cause of anemia than hitherto recognized. Not only oxidant drugs, but diabetic ketosis, pneumonitis, and viral hepatitis as well, have precipitated hemolysis in patients not receiving drugs.^{2,3}

Altogether, at least 24 human erythrocyte variants of glucose-6-phosphate dehydrogenase have been defined, on the basis of electrophoresis, substrate specificity, Michaelis constants, and so forth. Some of the features that distinguish these variants have been indicated by Lerner and Doscherholmen.¹ Major variants associated with low glucose-6-phosphate dehydrogenase levels may be designated: (1) Negro variant; (2) Mediter-

ranean variant; (3) Greek mild variant; (4) undefined variants (for example, Malayan) and (5) congenital nonspherocytic hemolytic anemia variants.

As illustrated by the case reported,¹ glucose-6-phosphate dehydrogenase deficiency is not restricted to any ethnic group, although the gene frequency in those of north European ancestry is only about 1 in 1,000. Except for one case⁴ of a Japanese patient, congenital nonspherocytic hemolytic anemia due to glucose-6-phosphate dehydrogenase deficiency seems to have been recognized almost exclusively in Caucasians, particularly those of north European ancestry. Congenital nonspherocytic hemolytic anemia is of interest in other respects. Qualitative enzymatic changes seem to be almost unique to each affected family.⁵ A puzzling feature has been that heterozygotes* with this disorder most commonly show entirely normal glucose-6-phosphate dehydrogenase levels. This was true of the patient described by Lerner and Doscherholmen¹ and has been true in our experience with three of four families in which males were affected with congenital nonspherocytic hemolytic anemia due to glucose-6-phosphate dehydrogenase deficiency. This phenomenon has led experienced investigators⁶ to postulate that this deficiency in their patient with congenital nonspherocytic hemolytic anemia represented a new mutation rather than hereditary transmission. Other more plausible explanations are that in a woman heterozygously affected with this disorder, (1)

*"When I couldn't even smell corned beef and cabbage,
I decided it was time for you, Doc."*

Maybe he doesn't know when he's well off. But you might want to prescribe long-acting Novahistine LP anyway.

Two tablets in the morning and two in the evening will usually provide day and night relief by helping to clear congested air passages for normal, free breathing. Novahistine LP is formulated to provide continuous therapeutic effect for 8 to 12 hours. The decongestant ingredients help restore normal mucus secretion and ciliary activity—physiologic defenses against infection of the respiratory tract.

Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result. Each Novahistine LP tablet contains: phenylephrine hydrochloride, 25 mg., and chlorpheniramine maleate, 4 mg.

NOVAHISTINE® LP

PITMAN-MOORE Division of The Dow Chemical Company, Indianapolis

the affected erythrocyte cell line may proliferate less efficiently than the normal cell line, (2) the affected cells may be more rapidly eliminated from the circulating blood, leaving only unaffected erythrocytes in circulation, or (3) that due to uniform embryonic inactivation of the abnormal x chromosome, only normal erythrocytes may be found in the blood. Probably all of these mechanisms contribute to making many heterozygous females indistinguishable from normals.

In the past, some patients with congenital nonspherocytic hemolytic anemia due to glucose-6-phosphate dehydrogenase deficiency have been subjected to splenectomy, and in some of these this therapy was based on the results of osmotic fragility studies. Although splenectomy is "curative" in congenital spherocytosis, it has been of little or no benefit in glucose-6-phosphate dehydrogenase deficiency, and infrequent-

ly of benefit in other hemolytic disorders due to enzyme deficiency. Furthermore, infectious or thromboembolic phenomena which occasionally follow splenectomy may lead to morbidity or death. Osmotic fragility is a nonspecific test, the results of which are usually normal in congenital nonspherocytic hemolytic anemia, but may not be decisive. It would seem, then, that one of the many reliable methods for detection of glucose-6-phosphate dehydrogenase deficiency, which can be done in any hematology laboratory, should be applied in all cases of congenital hemolytic disease wherein any question exists as to the underlying mechanism. If glucose-6-phosphate dehydrogenase deficiency is confirmed, splenectomy should not be performed, transfusions should rarely be administered, and exposure to drugs should be carefully restricted.

Food Allergy

MANY AREAS in the practice of clinical allergy are controversial and this is especially true of problems relating to food allergy. There is no doubt that allergy to foods may be important etiologically in many clinical conditions. The question is how this problem can best be approached from a diagnostic standpoint, since treatment is clear as to removal of the offending foods once a definite diagnosis has been made. Diagnostic tests, in general, are on a shaky scientific foundation. Skin testing for offending foods has been found to be generally unreliable. Elimination diets are sometimes helpful. A carefully taken clinical history is certainly important, but patients often are uncertain

as to the importance of various foods. A provocative diet containing large amounts of the suspected food given on several separate occasions may be a valuable technique. Another type of testing involves the leukopenic index which is based on the unproved idea that leukopenia follows the ingestion of a food to which a patient is allergic.

In the article concerning corn allergy in the present issue, Dr. Johnson* has used the Rinkel technique of giving injections as a test for food allergy and then giving "neutralizing" injections of the same material. This method of diagnosing food allergy has been controversial and the scientific basis is not well established. One cannot deny that Dr. Johnson's patients have benefited

Eczema of many years... controlled in two weeks

Before treatment

After treatment —
with ARISTOCORT Topical
Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side

effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive non-permeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyoderma will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Available in 5 Gm. and 15 Gm. tubes and ½ lb. jars.

from his treatment. However, as in most studies in food allergy, controls are lacking. Symptoms which Dr. Johnson described as "throat feeling thicker, something in throat, formation of phlegm in throat, need of clearing of throat, sinus drainage in throat, postnasal drip, runny nose, stuffy nose and throat, dry throat, dry mouth and nose, cough, frothy saliva" may or may not be related to food allergy. The psychologic impact on a

patient of a rigorous program of testing and then elimination of foods is not clear. Judgment in regard to use of the Rinkel technique of diagnosis and treatment of food allergy is not possible because adequately controlled studies have not been carried out.

Rochester, Minnesota

The Use of Drugs in Mild Hypertension*

ARE ALL OR nearly all hypertensive patients benefited by a pharmacologically-induced normotensive state? This is one of the crucial questions for those interested in hypertension today. It has been established beyond doubt that hypertensive patients have a poorer prognosis for life expectancy than do nonhypertensive patients, and that the severity of the hypertensive disease largely determines the prognosis. There can be little argument about the benefits of antihypertensive therapy in patients with malignant or accelerated hypertension; nor is there much doubt that treatment will improve the prognosis in those patients whose hypertension has produced certain complications in the cardiovascular-renal systems (if renal complications, in particular, are not too far advanced). Mildly hypertensive patients also have a shortened life expectancy, but it remains to be proved conclusively what effect treatment will have on this group of patients. Evidence to date suggests that treatment will be beneficial in preventing or significantly retarding the development of complications that shorten the lives of mildly hypertensive patients, but the hypothesis has not been proved to the complete satisfaction of physicians and others concerned with this problem. The final answer may await results of a carefully controlled, long-term prospective study.

It appears that the beneficial effect of anti-

hypertensive treatment relates to lowering of the systemic blood pressure. Whether this is produced pharmacologically by reducing the peripheral vascular resistance or by reducing cardiac output, whether by interfering with the function of the sympathetic nervous system or by altering sodium metabolism, appears to matter little so long as the systemic blood pressure is reduced.

Were the ideal antihypertensive drug available, one could advocate drug therapy for all hypertensive patients regardless of the severity of the disease. However, all drugs currently in use have potentially harmful effects in addition to the desired antihypertensive actions. In many ways, the thiazide drugs and related agents approach the ideal as antihypertensive drugs. The recent report by Moyer again underscores the applicability of these agents in everyday clinical practice. Yet alteration of carbohydrate metabolism, hyperuricemia, and hypokalemia, which are among the undesired effects, are worrisome, particularly in considering the possible use of these drugs in a patient for 10, 20, or more years. Consequently, the physician who is treating mildly hypertensive patients must weigh carefully the hazards of the disease as they are known against the hazards of drug therapy in his attempt to arrive at the best solution of whether to treat or not to treat.

Optimism

I make the most of all that comes
And the least of all that goes.

Sara Teasdale

"All Interns are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards; they all are underpaid, too. Therefore, all interns are alike.

That's utter nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* in-

volving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to stay strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all interns aren't alike, either.

Serious Bleeding During Therapy with Coumarin Compounds

IN THE NOVEMBER issue of MINNESOTA MEDICINE there appears an article entitled "Coumarin Complications" by Reece and Olson.* The authors report eight cases of serious bleeding occurring during therapy with coumarin compounds, with three fatalities. Such a report re-emphasizes the fact that there is risk of serious and possibly fatal hemorrhage when anticoagulant therapy with coumarin compounds is employed. The authors include pertinent comments on the clinical manifestations which may lead to the diagnosis of serious internal hemorrhage in unusual locations.

It seems worthwhile to emphasize the fact that the prothrombin time was well in excess of what is usually considered the upper limit of the therapeutic range in seven of the eight reported cases, when the serious bleeding developed. For a good many years the upper limit of the range of therapeutic hypoprothrombinemia during therapy with coumarin compounds has been considered by most clinicians who have had experience with this type of therapy to be indicated by a one-stage prothrombin time which is two and one half times the normal prothrombin time in seconds. This corresponds roughly in most laboratories to a prothrombin activity which is approximately fifteen per-cent of normal. Many clinicians feel that for long-term therapy the upper limit of the therapeutic range should be even lower, that is, indicated by twice the normal value of the prothrombin time in seconds.

Intravascular thrombosis is a potentially lethal and potentially disabling disease process. There is evidence that it can be prevented or arrested in the majority of cases by adequate anticoagulant therapy. However, after twenty-five years of employment of this method of treatment there is still controversy and disagreement as to just when it should be used. The important thing is for the physician to treat patients and not diseases. Patients should be selected for anticoagulant therapy only after careful consideration of

all facts which might lead to its success or failure.

It has been generally agreed by most experienced clinicians that there are three basic prerequisites for the employment of anticoagulant therapy: an interested and meticulous physician, a patient who is willing and able to follow instructions without deviation, and a reliable laboratory. A primary consideration in the avoidance of serious hemorrhagic complications during anticoagulant therapy is to keep the prothrombin time within the therapeutic range. This requires that determinations of the prothrombin time be done as frequently as is necessary for determining the proper dose of the drug for the individual patient. Maintenance of the prothrombin time within the therapeutic range also requires, as indicated by the authors, particularly close supervision of the patient if there is intercurrent illness, temporary nutritional deficiency, or the employment of other drugs such as salicylates, certain antibiotics and steroids, any of which may augment the action of the coumarin compound.

Most of the severe bleeding complications of coumarin therapy have occurred during periods of excessive hypoprothrombinemia, but it is true that some have occurred when the prothrombin time was within the therapeutic range. Minor but definite bleeding occurring in such patients should always be viewed with suspicion, and serious consideration should be given to discontinuing the anticoagulant therapy. A small group of patients may be encountered whose response to anticoagulants is found to be erratic and fluctuating in spite of frequent prothrombin time determinations and careful attention to dosage. Such patients are rather poor subjects for long-term treatment.

The use of anticoagulants can be a valuable therapeutic tool in the hands of an experienced and careful physician. The indications for its use should be clearly evident. Once treatment is begun it should be continued only if it can be

Chronic Fatigue

In our precious cabbage patches the holometabolous insecta are the hosts of parasitic polyembryonic hymenoptera, upon the prevalence of which rests the psychic and somatic stamina of our fellow-countrymen.

—William Osler

Buckle Up

Smartest thing to wear on your summer vacation is a seat belt. A recent University of Michigan study, financed by the U. S. Public Health Service, indicated the regular use of seat belts by drivers and passengers could have prevented 12,000 traffic deaths in 1965.

Yet last year's annual seat belt survey conducted across the nation during Vehicle Safety-Checks revealed some disturbing figures. Of the 1.7 million cars checked in the survey, more than half were equipped with seat belts. Yet nearly two thirds of the drivers questioned failed to use them when most needed—within 25 miles of the driver's home where four out of five traffic accidents occur.

Boston Tea Party Relived

Nearly two hundred years ago a minority who were in disfavor of King George III decided to have a party to talk among themselves and let off some steam. Through the ensuing years and down through the pages of history this eminent gathering came to be known as the "Boston Tea Party."

Subsequent to this famous (or notorious) social gathering there arose gross dissatisfaction with the domineering interference by our mother country, and thus was born the American Revolution. History records the fact that we won the war and a free nation was born.

The laws of this free nation are based upon a "Constitution of the United States of America." Within this Constitution was inserted a "Bill of Rights." There have been instances, and there will be still more instances where the laws must be modified or changed for the progress and growth of a great nation.

Now, in our latest law, we are again at the threshold of changes involving the lives of millions of people. We have now formulated and instituted a law giving medical aid to every individual at such time as he attains age 65.

We do not have the fiscal wherewithal to support this program; consequently the "providers of service," as well as the physicians, will be forced to accept fees based upon governmental directives. These fees will be so minimal that the government will then have an excess (on paper only however). At this point a greater number of persons—in categories hitherto not covered—will then become eligible for care. Our individual practices will become completely engulfed in governmental directives.

Like the "Boston Tea Party members," there are only a few of us actively participating to get the law modified—particularly that part which encompasses our welfare recipients.

Unlike the "Boston Tea Party," we will not cause a revolution involving bloodshed. We would like to start an avalanche—an avalanche of letters to governmental officials who have the power to modify or change a law.

Aristotle was correct in his theory when he intimated that the young man was generally too didactic; the middle aged man, who had mellowed and become more pensive with age, had learned to negotiate; and the old man, ready to retire, was complacent in his attitude and willing to accept whatever came his way.

I cannot believe that our peers in the medical profession can be so complacent as to leave as a legacy to those who have so admired them, a record of having done nothing in our great battle for the individual doctor-patient relationship such as they have hitherto enjoyed.

If we must lose this debate with our welfare departments we will have lost one more freedom. Where will it end?

The Editor's Soliloquy

For Whom Does the Bell Toll?

Living is a physiologic process in which the body is geared to provide its own generator. It has its numerous built-in mechanisms which, under normal circumstances, function well, even when we tax it beyond its normal endurance: a feat impossible for any man-made device.

The dietary inadequacies of three or four generations ago undoubtedly contributed to the smaller stature of our grandparents as compared with the increased stature of the draftees in World War II; but the other privations forced upon those earlier generations no doubt functioned to the advantage of later generation by evolving a better stock through the survival of the fittest.

Now that we have attained this biological pre-eminence, must we corrupt our heritage by over-indulgence in the luxuries our bountiful civilization provides—with its built-in opportunities for indolence and intemperance, as we shift from chaise longue to armchair while sipping our beer, munching our pretzels, and patronizing the most appealing of the carcinogen ads! Instead of being the beneficiaries may we not become the victims of our opulence—with its siren call to self-gratification!

The triple dualities of accidental death via alcoholism, cardiovascular disease via overweight, and cancer via carcinogens, contribute both clinically and statistically the major causes of death in our generation. On the death certificate alcoholism as a contributing factor to accidental death is acceptable; but do overweight or excessive smoking ever appear as accessory causes of cardiovascular disease or lung cancer?

Recently we have been reading about a colony of centenarians in an Aztec tribe in Peru, whose members do not eat, drink, or smoke to excess but live simple lives, maintain regular habits, and engage in daily physical activity. There may be those among us who ask: "Who wants to live that way and who wants to live that long!" But this very question, implying as it does a negative answer, shows how far we have deviated from the wholesome norms of moderation, a virtue fast becoming a casualty of our affluence. Unless we practice more of it, biological regression will be our fate. Nor need we then ask for whom the bell tolls. We shall know!

Carl O. Rice, M.D.

Old Doc Hess says: Some people talk to conceal themselves.

Habit is like a soft bed—easy to get into but hard to get out of.

Mucormycosis

QUESTION: I referred a patient for thoracic surgery. A left upper lobectomy was performed for bullous emphysema. A copy of the pathologist's report has been sent to me in which it is related that organisms resembling mucormycosis were seen on permanent sections of the lung. What is the significance in the finding of such mucormycosis organisms as described?

ANSWER: In reported human cases *Rhizopus* rather than *Mucor* has been the pathogenic fungus. It is an ubiquitous* organism and is a frequent culture contaminant. As a pathogen it is characterized by its great affinity for spreading to blood vessels. The arteries particularly may become involved, with the formation of a purulent arteritis and thrombosis. It tends to affect specifically diabetics who are poorly controlled. The disease may manifest itself in several forms. The pulmonary form may be primary or hematogenous in origin with thromboses of the pulmonary vessels taking place. As a result, pulmonary infarcts and lobular pneumonia may occur. In the absence of such clinical manifestations in the case described it is not likely that the organisms are pathogenic.

I Chose Medicine

My sister and I decided that we must train ourselves to earn our living, for the family finances were rapidly diminishing and our only hope of a wide and full life, of going out into the big world, lay in our own efforts. There seemed only a few careers open to us—teaching, nursing, the practice of medicine. I chose medicine, not because I was scientifically-minded, for I was deeply ignorant of science. I chose it because as a doctor I would go anywhere I pleased—to far-off lands or to city slums—and be quite sure that I could be of use anywhere.

The Viewing Box

Traumatic Obstruction of the Duodenum

ON SEPTEMBER 22, 1966, a twenty-nine-year-old white male was driving a truck that struck the rear of a bus. In the accident he was thrown against the steering wheel. The patient presented with rather severe upper abdominal pain, but no nausea or vomiting. He was admitted to the hospital for observation. Admission roentgen study showed a minor degree of localized paralytic ileus involving the upper abdomen. Serum amylase was normal and the hemogram was unremarkable. The patient tolerated liquids and a soft diet very well. He became symptom-free within twenty-four hours and was discharged.

On September 29, 1966, the patient began to experience postprandial episodes of upper abdominal pain associated with a feeling of fullness. On two occasions vomiting occurred. This relieved the feeling of fullness and alleviated the abdominal pain. An upper gastrointestinal barium study was done on October 3, 1966. This examination revealed moderate dilatation of the stomach and proximal duodenum due to partial obstruction in the third and fourth portions of the duodenum (Arrows, Figure 1). There was an irregular constriction of the distal

Figure 1

Continued

THE VIEWING BOX

duodenum with distorted coarsened mucosal pattern (Arrows, Figure 2). The patient was admitted to the hospital and treated conservatively with gradual increase from a liquid to a soft diet. Within five days he became asymptomatic and was discharged.

Figure 2

Following discharge from the hospital the patient remained symptom-free. On October 21, 1966, he had a repeat upper gastrointestinal study. This examination showed clearing of the gastric and duodenal dilatation. Only minimal irregularity of the lumen and mucosal pattern remained in that portion of the duodenum which had shown constriction and a stretched mucosal pattern (Arrows, Figure 3).

Figure 3

The patient has remained asymptomatic to the present time. He was scheduled for another gastrointestinal study the latter part of March, 1967. What is your diagnosis? (See next page.)

Diagnosis: Intramural duodenal hematoma

The clinical course and radiographic findings in this case are consistent with a diagnosis of intramural duodenal hematoma. Trauma to the duodenum resulting in intramural hematoma is being recognized and reported with increasing frequency. The classic insult is forceful impact against a steering wheel; however, even light blows may cause injury. The postbulbar portion of the duodenum is retroperitoneal and is firmly attached to surrounding structures. It has points of acute angulation and often a fluid content, factors which make the duodenum vulnerable to blunt trauma with compression against the vertebral column.

Intramural hematomas may involve the duodenum from below the ampulla of Vater to the ligament of Treitz and may even involve the proximal jejunum. The total involvement is usually ten to twenty centimeters in length. In cases where duodenal resection was deemed necessary, the surgical specimen showed an edematous, hemorrhagic serosal surface with severe distortion of the muscularis by hemorrhage.

Symptoms following trauma may be immediate; however, there is commonly a latent period of days or weeks between the time of trauma and the clinical and roentgenological manifestations. The chief symptoms are upper abdominal pain of varying severity and vomiting episodes which become more frequent. The history of blunt trauma to the abdomen and this symptomatology are prime indications for plain film study of the abdomen and especially gastrointestinal contrast study. This examination is diagnostic of obstruction. The specific nature of the obstruction can often be suggested.

The radiographic findings typically show varying degrees of gastric and duodenal dilatation proximal to the site of obstruction. The obstruction may be partial, which is the usual situation, or rarely complete. At the site of the intramural hematoma, one of two appearances may be noted: The first of these is the irregular constriction of the lumen with associated widening and irregularity of the mucosal folds; the other is the typical coiled spring stretching due to flattening of the valvulae conniventes by the hematoma.

Other causes of intramural duodenal hematoma besides trauma are pancreatitis, carcinoma of the pancreas, and bleeding diatheses such as hemophilia and anti-coagulant therapy. One other cause recently reported is an iatrogenically-produced intramural duodenal hematoma due to a per-oral small-bowel biopsy with a Ross biopsy capsule.

Consideration must also be given to the occurrence of associated trauma to other organs. Approximately fifty per cent of the cases of intramural duodenal hematoma are associated with some degree of trauma to the pancreas. Fractures of solid viscera such as the liver, spleen, and kidneys may occur. Out-right rupture of the duodenum may also occur, usually at the junction of the second and third portions. Air and blood from the site of the rupture may pass either retroperitoneally or intraperitoneally. Occurrence of associated injury to other intra-abdominal organs obviously compounds the difficulties of diagnosis.

Venereal Disease A Serious National Problem, Says AMA

Venereal disease is spreading so rapidly that it now represents this nation's most urgent communicable disease problem.

VD is hitting particularly hard among teenagers and young adults, according to the American Medical Association.

The venereal diseases are infecting about two Americans a minute—3,000 a day, or 1,100,000 a year. Cases of infectious syphilis have almost tripled in this country in the past five years. More than a million

new cases of gonorrhea are developing annually.

VD can blind, cripple, and even kill.

The ravages of venereal diseases are all needless tragedy, says the AMA, because both syphilis and gonorrhea can be avoided. If contracted, they can be cured by prompt medical treatment.

The cure for both diseases—penicillin—has been available since 1943. Any family physician or public health clinic can administer

prompt treatment.

Venereal disease is caused by intimate personal contact.

Complacency, ignorance, and a free-and-easy attitude toward moral standards are partly responsible for the spread of VD; the increasing use of alcohol, especially among young people, also plays a role.

Authorities believe, however, that thousands of young people simply aren't aware of the dangers of VD. Once infected, they are complacent about treatment.

One of the first signs of syphilis may be a painless, ulcerating sore. Gonorrhea produces inflammation of the genital and urinary tracts, and a discharge of pus.

A person may contract syphilis and be unaware that he has the disease. After the first symptoms, the germs may remain hidden in the body for as long as 20 years before any damage is discovered. Then the person may become crippled, develop heart disease, blood vessel disease, blindness, or show mental symptoms. Even death may result from this hidden stage of syphilis.

If left untreated, gonorrhea may be responsible for arthritis, endocarditis, sterility, and blindness.

If a person suspects he may have contracted venereal disease, he should go to a physician immediately.

VD should be treated promptly by a physician.

Tumor Conference

Mucocele of the Appendix and Jelly-Belly (Pseudomyxoma Peritonei)

MUCOCELE OF the appendix is not regarded as a true neoplasm. It is usually considered a cystic dilatation of the terminal appendix due to cicatricial obstruction of the proximal appendix. The thin-walled mucocele is generally filled with thick mucus. The mucous membrane has usually been replaced by a single layer of mucus-producing cells or glands similar to those found in the colon. Rupture of a mucocele and spillage of its contents may result in the spread and growth of mucus-secreting cells over the peritoneal surfaces with the secondary accumulation of gelatinous mucus in the peritoneal cavity (pseudomyxoma peritonei). There is no agreement as to whether pseudomyxoma peritonei is only a non-neoplastic proliferation of mucosal cells stimulated by irritation or a true neoplastic epithelial proliferation.

Neither mucocele nor pseudomyxoma peritonei is common. Incidence is reported as follows^{1,2,5}: (a) 2 to 4% of all appendiceal tumors are mucocèles; (b) appendiceal tumors are found in 0.3 to 1% of all removed appendices; (c) appendiceal tumors constitute 0.1% to 0.2% of all intestinal neoplasms. Since mucocele of the appendix is a rare entity, a recent case prompted us to review the experience with mucocèles (and the even rarer cases of pseudomyxoma peritonei) at the Minneapolis Veterans Administration Hospital.

This case of a mucocele illustrates the frequent presenting complaint of a right lower quadrant mass in an otherwise asymptomatic patient.

Case Reports

Case I

A 40-year-old man, whose private physician found a palpable, round, nonfixed mass measuring 5 cm. in diameter in the right lower quadrant of his abdomen on routine examination in April 1964, refused to have the recommended surgery at that time. The patient's only symptoms were fullness and tightness in his right lower abdomen. Two barium enemas, one in April 1964 and a second in October 1964, did not show any abnormality of the colon. The patient continued symptom-free and was followed by his physician at six-month intervals. The mass persisted.

Laboratory and X-ray Findings

The patient was admitted to the hospital in July 1966. All laboratory work was within normal limits: hemoglobin, leukocyte count, prothrombin time, blood urea nitrogen, fasting blood sugar, serum proteins, alkaline phosphatase, sugar glucose tolerance, bilirubin, serum electrolytes and multiple stools for occult blood. On lumbosacral spine films a calcific

Continued

TUMOR CONFERENCE

density was seen lateral to the spine at the level of L5-S1 (Figure 1). A barium enema showed an irregularity of the posterolateral wall of the cecum, suggestive of adenoma or a carcinoma (Figure 2). A chest film, an intravenous pyelogram, and an electrocardiogram were normal.

Fig. 1 — This abdominal film shows the unusual calcification overlying the iliac bone. The calcification was in the area of the palpable mass.

Fig. 2 — A barium enema shows the deformity of the cecum.

Operative Findings

At surgical exploration in December 1966, a 10 x 6 x 6 cm. mass was found in the right lower quadrant, arising from the appendix and adherent to the cecum and psoas muscle. The tumor was excised widely with 15 cm. of cecum and right colon and 8 cm. of ileum. Continuity was restored with an iliotransverse colostomy. Sections through the proximal appendix, cecum and ileum were normal. Sections through the lesion in the distal retrocecal appendix showed fibrous walls lined by simple columnar epithelium. The mucous material contained rare clumps of morphologically, benign columnar cells. After an uneventful post-operative course, the patient is currently being followed in our Out Patient Department. He has probably been cured.

Since 1941 seven mucocèles of the appendix and three cases of pseudomyxoma peritonei have been seen at the Minneapolis Veterans Administration Hospital. All the patients were men between 28 and 74 years old. Of the seven mucocèles, one unusual case was associated with a proximal carcinoid. Two cases were found incidentally at autopsy; another was found incidentally during a gastrectomy for duodenal ulcer disease. Only one presented with the symptoms and signs of an acute appendicitis. The remaining two patients were operated on because of palpable right lower quadrant abdominal masses. None of the seven mucocèles had ruptured. The five patients, whose diagnosis was made during life, have been seen at the Minneapolis Veterans Administration Hospital in follow-up clinic and are free of recurrent disease for one month in the most recent case to twelve years for the longest follow-up. This curative result for the unruptured mucocèle of the appendix has been found in other series^{1,3,4}.

One group,⁴ studying 136 mucocèles of the appendix with benign epithelium, found no cases of pseudomyxoma peritonei despite an occasional spillage of the

MUCOCELE OF THE APPENDIX

mucocoele contents. Pseudomyxoma peritonei arose secondarily only from those mucocoeles which had been found to contain "Grade I" adenocarcinoma.

The good results of benign mucocoele are contrasted with the unfortunate course of pseudomyxoma peritonei. One brief case history of a typical pseudomyxoma shows some of the problems encountered.

Case 2

A 72-year-old white man had an appendectomy in 1941 at another hospital. Following the operation he was informed that the appendix had contained a "malignant tumor." He was seen postoperatively at regular intervals with no evidence of recurrence until 1964. At that time he noticed gradual abdominal distention, but no other symptoms. He was first seen at our hospital in July 1966. At laparotomy on July 15 the peritoneal cavity was filled with 12,000 cc. of gelatinous material along with many peritoneal implants (Figure 3). After evacuation of the gelatinous material 30 mgm. of nitrogen mustard were instilled intraperitoneally. A month later another 1,500 cc. of gelatinous material was removed by paracentesis followed by intraperitoneal instillation of 22 mgm. nitrogen mustard. The patient's condition deteriorated rapidly and he expired on September 24, 1966. Death was thought to be due to the advanced stage of the disease rather than to the nitrogen mustard administration. The long period (25 years) between the appendectomy and his final episode is certainly noteworthy. It would raise the question as to whether the appendix was the site of origin in this case.

The course of the other two patients with pseudomyxoma peritonei were as fol-

Fig. 3 — This picture taken at surgery shows the many peritoneal implants seen after evacuating the abdomen.

Continued

TUMOR CONFERENCE

lows: One man, 73 years of age, was well until six months prior to admission. His disease progressed rapidly and at the time of admission far-advanced disease prevented anything except supportive, terminal care. The third patient with pseudomyxoma peritonei was found to have his disease during a routine inguinal herniorrhaphy. A subsequent laparotomy showed a ruptured mucocele of the appendix for which a cecectomy was done. At the present time, 3½ years later, there has been no recurrence.

The spectrum of pseudomyxoma peritonei at the favorable end shows a process in which there is leakage of cell-free mucus into the peritoneal cavity from a benign mucocele. If the mucocele is excised, the condition usually regresses spontaneously.^{1,3,4,5} On the other end of the spectrum is the mucocele with an epithelium consisting of malignant cells. This type spills mucus-containing malignant cells which implant themselves on the peritoneal surface and abdominal organs and continue to grow regardless of whether the primary site of origin is removed. Wide excision of the appendix proves curative in the first type, while in the latter, more radical surgery like omentectomy, cecectomy, colectomy, oophorectomy and peritoneal irrigations with nitrogen mustard have only rarely produced long-term survival^{2,4}.

Medical Seminar

The Immunoglobulins

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

CONSIDERABLE PROGRESS has been made recently in the characterization of the chemical structure and function of antibodies. With this rapid progress has come a certain amount of confusion, in part as a result of varying terminology. The terms (Table 1) recommended by the World Health Organization Committee on Nomenclature of Human Immunoglobulins¹ will be used throughout this review.

Historical Aspects

The acquisition of knowledge about the immunoglobulins has depended on specific technical achievements which opened new avenues of investigation. Among the more important of these technical developments are electrophoresis, ultracentrifugation,* immunodiffusion, and immunoelectrophoresis.

Electrophoresis

Proteins migrate in an electric field at a rate largely dependent on the surface charge of their molecules. Since proteins differ markedly in their net molecular charges, they differ also in their "electric field" mobility at any given pH value. In 1937 Tiselius employed these principles in developing his technique of moving-boundary electrophoresis. By such a technique it was shown that serum proteins could be divided into five fractions: albumin, and α_1 -, α_2 -, β -, and γ -globulins. Shortly thereafter, Tiselius and Kabat² immunized animals and observed an increase in the γ -globulin peak concomitant with increasing antibody titers. When the antibodies were precipitated from the serum by their specific antigens, the γ -globulin concentrations returned to

preimmunization levels. Thus it was shown that humoral antibodies were located in the γ -globulin fraction.

Ultracentrifugation

In 1926 Svedberg and collaborators devised an instrument for obtaining centrifugal fields of sufficient intensity to cause separation of large molecules in solution. Heterogeneous protein solutions could thus be separated on a basis of the different sedimentation rates of the various proteins; the sedimentation rates depend on the size, shape, and density of the molecules. The technique of ultracentrifugation was combined with electrophoresis in studying the γ -globulins by Deutsch and co-workers³ in 1946. Two main components with different molecular sizes and sedimentation coefficients were identified within the γ -globulin family. Small molecules (7S) comprised the larger fraction; the remainder was composed of 19S macromolecules.

Immunodiffusion

In 1946 the technique of immunodiffusion, first used by German workers in 1905 and then discarded, was revived and perfected. The impact of this technique on the developing sciences of immunology and immunochemistry cannot be

overemphasized. Before this time, in-vitro methods of detecting reactions between soluble antigen and its specific antibody consisted of the demonstration of precipitation or flocculation in a fluid medium. Unfortunately, the antigens used were frequently impure; and the flocculate, or precipitate, being examined often consisted of a mixture of many antigen-antibody complexes. Prior to the revival of immunodiffusion techniques, there was no simple method available to detect such impurities or contaminants. The technique of immunodiffusion is simple and extremely sensitive. In brief, antigen is permitted to react with antibody in a gel medium in which each substance diffuses at a rate determined by its concentration and its own specific diffusion coefficient. A line of precipitate forms when an antigen encounters its antibody; this line becomes most pronounced and fixed at the specific location in the gel where equivalence occurs—that is, at the point where the reacting antigen and antibody reach proportions optimal for precipitation. Because of differences in diffusion rates, complex antigen-antibody systems can be resolved in precipitin lines that are distinctly

separated.

Oudin⁴ described a method of test-tube immunodiffusion in 1947. Antiserum was mixed with a warm solution of agar, and the agar was allowed to solidify in a test tube. Antigen solution was then layered on top of the gel and allowed to diffuse into the gelled agar containing the antibody.

Ouchterlony⁵ introduced the important concept of comparative immunodiffusion. In his method, wells are cut in an agar plate equidistant from a central well. Antigen is placed in the outer wells, and the central well is filled with antiserum. The antigen and antibody diffuse into the agar and, on meeting, form a line of precipitation. Ouchterlony noted three principal types of reaction, depending on the relationships between the antigens and antisera used. If the antigens in neighboring wells are identical, the precipitin lines fuse at their contiguous ends; this is termed "reaction of identity" (Figure 1-a). If neighboring wells contain unrelated antigens and the central well is filled with antisera against both, the precipitin lines cross in a "reaction of nonidentity" (Figure 1-b). The final pattern has been

Fig. 1 — Diagram of precipitin patterns obtained by Ouchterlony immunodiffusion technique. (a) Reaction of identity. (b) Reaction of nonidentity. (c) Reaction of partial identity.

termed "reaction of partial identity" (Figure 1-c) and occurs when an antiserum to a complex antigen reacts with neighboring wells, one of which contains the complex antigen, while the other contains a component of but not the complete antigen. Under these circumstances, fusion occurs between the precipitin lines of the identical subfractions; the nonidentical fraction fails to fuse and instead forms a spur from the point of fusion. From study of precipitin patterns on Ouchterlony plates, one can deduce the various types of relationships in complex antigen-antibody mixtures.

Immunoelectrophoresis

In 1953 Grabar and Williams⁶ incorporated the principles of electrophoresis and immunodiffusion into the very important technique of immunoelectrophoresis. Electrophoretic migration is performed in agar gel; immunodiffusion is then accomplished by adding antiserum to a trough cut in the gel alongside and parallel to the field of electrophoretic migration. A series of precipitin lines form as the separated serum protein fractions, diffusing in a radial manner, make contact with the linear margin of the immune serum advancing from the trough. The position of these precipitin lines is determined by the electrophoretic mobility, rate of diffusion, and serologic specificity of each of the proteins present. The technique of immunoelectrophore-

sis can be further manipulated to advantage by using more refined antiserum; for example, specific anti-albumin serum will form a precipitin line only with albumin, anti-transferrin will react only with transferrin, and purified anti- γ -globulin will react only with the γ -globulin fractions of the serum being studied.

Immunoglobulin Subclasses

With the use of these techniques, the complexity of the antibody-containing serum fraction could be studied. It was found on immunoelectrophoresis that this fraction consists of three major groups of proteins now known as IgG (γ G), IgA (γ A) and IgM (γ M) (Figure 2). The IgG fraction is the largest (70%) and has the widest range of electrophoretic mobility, extending from the γ to the α_2 region. IgA (21%) and IgM (7%) migrate in the β - γ area. Two other subclasses have recently been identified in minute quantities in normal human serum and have been named IgD and IgE. Thus the term " γ -globulin" is obviously no longer adequate for this complex mixture of proteins. The more appropriate designation "immunoglobulins" has gained wide acceptance and was recommended by the WHO Committee on Nomenclature.¹ By definition, the immunoglobulins include all proteins with antibody activity plus certain proteins related to them by chemical and antigenic speci-

Fig. 2 — Diagram of distribution of immunoglobulins in normal human serum after electrophoresis and after immunoelectrophoresis (Inset). Lines are projected from the immunoelectrophoresis onto the electrophoretic pattern. The areas under these lines indicate the relative amounts and electrophoretic distributions of IgG, IgA, IgM, and IgD.

Continued

ficity. Related proteins, for which antibody activity has not been demonstrated, include the myeloma proteins, Bence Jones proteins, and naturally occurring subunits of the immunoglobulins.

The various subclasses of the immunoglobulins can be isolated from serum by involved physicochemical procedures which include precipitation by organic and inorganic agents, preparative electrophoresis and ultracentrifugation, ion-exchange column chromatography, and gel filtration.

The known properties of these various subclasses are listed in Table 2. Certain specific functions have now been identified for most of the immunoglobulin subclasses.^{7,8}

IgG

This subclass contains many of the recognized antibodies, both to bacteria and to viruses, as well as the factor responsible for the lupus-erythematosus cell phenomenon. All IgG antibodies are actively transported across the placenta.

IgA

The IgA immunoglobulins include antibodies against insulin in persons with diabetes and against thyroglobulin in persons with thyroiditis; however, these antibodies have also been identified in the IgG and IgM subclasses. Antibodies against ragweed and *Brucella abortus* are also of the IgA variety. A special form of these globulins is present in secretions (saliva, colostrum, and bronchial secretions).⁹ More than 90% of the immunoglobulin in secretions is of the IgA variety as opposed to 21% in the serum.¹⁰ The secretion IgA differs from the serum IgA in having an additional piece on its molecule; the function of this moiety has not been determined.

IgM

Immunoglobulins formed in the newborn belong almost exclusively to the IgM subclass. In later life, IgM immunoglobulins are usually the first antibodies to appear after antigenic stimulation and are rarely associated with immunologic

TABLE 2
Properties of Immunoglobulins

Property	Subclass

memory. The IgM subclass contains the isohemagglutinins, cold agglutinins, rheumatoid factor, antibodies against somatic O antigens of gram-negative bacteria, heterophil antibodies, and Wassermann antibodies.

IgD

This subclass was recently identified by Rowe and Fahey¹¹ in a patient with a myeloma protein that did not react with known myeloma antisera (anti-IgG, anti-IgA, or anti-IgM). Antiserum was prepared for this unique protein and tested against normal human sera; it was found that normal human serum contains minute quantities of these antigenically distinct immunoglobulins which have been named IgD.¹² Studies are now in progress to determine the immunologic function of the IgD immunoglobulins.

IgE

Quite recently, another subclass was described¹³ and tentatively named IgE. It apparently contains reagin activity previously thought to be associated with the IgA fraction.

Structure of the Immunoglobulin Molecule

The immunoglobulin molecule is a complex

*See Test Your Word Score Page 1097.

composite of structural and functional subunits.^{8,14,15} Many subunits have been identified, but their exact intramolecular positions and associations have not been determined with certainty. From available experimental information there is strong evidence that human IgG consists of four polypeptide chains (two light chains with molecular weights of about 20,000 and two heavy chains with molecular weights of approximately 52,000) held together by interchain disulfide bonds and noncovalent* interactions (Figure 3). It is surmised that each light chain is linked to a heavy chain by a disulfide bond and a third disulfide bond connects the two heavy chains. These disulfide bonds can be disrupted by reducing agents such as mercaptoethanol, thereby liberating the individual light and heavy chains. It is generally assumed that the participation of light and heavy chains in the structure of IgA conforms to that of IgG with the exception of the tendency of the IgA subclass to form polymers. It has recently been concluded that, at least in rabbits, IgM molecules are composites of five monomers, each having the "two light chain and two heavy chain" configuration. However, the heavy chains of IgM appear to be larger, with molecular weights in the range of 70,000.¹⁶

Each individual immunoglobulin molecule is symmetric, the participating light chains and

Fig. 3 — Porter model for IgG molecule. List in lower right shows known active sites on Fc fragment (see text).

Continued

heavy chains being identical. Dissimilarity of polypeptide chains has not been discovered within the molecule in nature although hybrid molecules have been synthesized *in vitro*. The light chains must be associated with a particular part of the heavy chains for the full expression of antibody-combining activity. Although not known for certain, it is thought that the carbohydrate component of the immunoglobulin molecule is associated with the heavy chains.

Light chains are of two antigenic types—type K and type L—which are common to all immunoglobulin subclasses and occur with a frequency of 70% for type K and 30% for type L. The light chains of the immunoglobulin molecule are indistinguishable from the Bence Jones proteins that occur in many patients with plasmacytic myeloma. The heavy chains are specific for each subclass; therefore they determine whether the molecule belongs to IgG, IgA, IgM, and so forth. It is also the heavy chains that confer on a particular immunoglobulin molecule its unique antibody specificity.

Further information relating structure to function was gained by studying the effects of the enzyme papain on the IgG immunoglobulin molecule. It was found that papain splits peptide bonds in the two heavy chains, releasing three fragments, one Fc and two identical Fab fragments (Figure 3). The Fab fragments were so named because each contains an active antibody combining-site formed by a light chain in association with a specific portion of the heavy chain. In addition, the Fab fragments have a specific genetic marker termed InV located on the light chains. On the Fc fragment—so named because this fragment is crystallizable—are located such functional groups as the site for complement fixation, the site for rheumatoid factor activity, and a factor regulating catabolism. Apparently IgG passes the placental barrier because of the presence of an active transport site on the Fc portion of its molecule; no such site is present in the IgA or IgM molecules. The Fc fragment also contains a genetic marker termed Gm.

Disorders of Immunoglobulins

The immunoglobulins are products of the complex and as yet not fully understood lympho-

cytic-plasmacytic series of cells. Consequently, disorders of the immunoglobulins are reflections of more basic abnormalities in their cellular system of origin. The immunoglobulin derangements can be divided into two broad categories: deficiency disorders and disorders associated with neoplasia.

In the light of clinical observations and recent experimental work on the thymus, a degree of order has been introduced into our concepts of the pathogenesis of the immunologic deficiency states. The specific immunoglobulin defects in these various disease states are shown in Table 3. Space does not permit further discussion of this involved and interesting subject which has been covered in a recent excellent review.¹⁷

Neoplastic proliferation of immunoglobulin-synthesizing cells usually results in the elaboration of paraproteins which appear in the serum or urine or both. The term "paraprotein" indicates that these proteins are structurally very similar to normal immunoglobulins; however, they are produced in excess and are usually restricted to a single molecular form. In addition, specific antibody function so far has not been demonstrated for any of the paraproteins. The paraproteinemias include plasmacytic myeloma, "monoclonal gammopathy" of unknown cause, Waldenström's macroglobulinemia, and heavy-chain disease.¹⁸

The protein abnormalities of plasmacytic myeloma are manifestations of alterations in protein synthesis in which a single type of globulin molecule or fraction thereof is formed by a clone of abnormal plasma cells. If the heavy chains and light chains are formed synchronously, an excess of whole molecules will appear in the serum as a myeloma peak. If there is asynchronism in chain production and light chains are produced in excess of heavy chains, there will be a myeloma peak concomitant with Bence Jones protein in the urine. If, in malignant dedifferentiation, the abnormal clone has lost the capacity to elaborate heavy chains, the only paraprotein to appear will be Bence Jones protein in the urine. Rarely (1% of cases), plasmacytic myeloma occurs without any detectable paraproteins. The frequencies with which the various paraproteins are observed are: IgG myeloma protein, 54%; IgA myeloma protein, 22%; Bence Jones protein

only, 23%. Bence Jones protein occurs in about 30% of cases with IgG or IgA myeloma protein.

Monoclonal gammopathy is an ill-defined group of paraproteinemias of unknown cause. It is sometimes associated with lymphomas or various carcinomas (rectum or prostate); occasionally it occurs without demonstrable underlying malignancy. This latter group may represent a latent phase of plasmacytic myeloma with the paraproteinemia preceding demonstrable plasma cell tumor by months or years.¹⁹

In Waldenström's macroglobulinemia, a more benign disorder than plasmacytic myeloma, excess protein, produced by abnormal "plasmacytoid lymphocytes," is associated with the IgM subclass. The increase in these macromolecules in the serum accounts for the hyperviscosity syndrome which is often seen in this disease.

Franklin's disease, or H-chain disease,²⁰ is a recently described paraprotein abnormality that presents clinically as a malignant lymphoma without evidence of bone involvement. The paraprotein, which has a molecular weight of approximately 55,000, occurs in the serum and in the urine. The urinary protein does not give the Bence Jones thermolabile reaction. Originally it was thought to be an excess of heavy chains, but it now appears that the paraprotein is more closely related, if not identical, to the Fc fragment of the papain digest.²¹

Summary

The basic principles of electrophoresis, ultracentrifugation, immunodiffusion, and immunoelectrophoresis are described as a necessary introduction to the subject of the immunoglobulins. Antibody activity is confined to this group of serum proteins, which presently includes five subclasses: IgG (γ G); IgA (γ A); IgM (γ M); IgD (γ D); and IgE (γ E). Specific antibody activities have been identified within each of the subclasses except IgD. There is strong experimental evidence that the basic immunoglobulin molecule consists of four polypeptide chains (two light chains and two heavy chains) held together principally by interchain disulfide bonds. The light chains are of two types, K and L, and are indistinguishable from the Bence Jones protein that may occur in plasmacytic myeloma. The heavy chains are specific for each immunoglobulin subclass. Light chains and heavy chains must be combined for expression of full antibody activity. The immunoglobulin deficiency states and the paraproteinemias (for example, myeloma, monoclonal gammopathy, Waldenström's macroglobulinemia, and heavy chain disease) are briefly discussed in the light of this recent knowledge.

Tandearil®

oxyphenbutazone

Therapeutic Effects: Tandearil is a nonhormonal compound which may rapidly resolve inflammation and help restore normal joint function. Its action does not affect pituitary-adrenal function or impair immune responses. Its value in osteoarthritis is especially noteworthy because this disorder responds inconsistently to steroids and is often resistant to salicylates. Further, indomethacin is limited only to osteoarthritis of the hip, whereas oxyphenbutazone is effective in all forms of the disease.

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should be closely supervised and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage. Make regular blood counts. Discontinue the drug and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, or a generalized allergic reaction may occur and require withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Osteoarthritis: The initial daily dosage in adults is 300-600 mg. in divided daily doses. When improvement occurs, dosage should be decreased to the minimum effective level; this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

Neurological Conference

Hemiparesis and Seizures in a Teenager

History

T HIS 17-YEAR-OLD boy was first referred to the University of Minnesota Hospitals in May 1965, for the treatment of a convulsive disorder. He had first experienced a grand-mal convulsion during a febrile episode at the age of 18 months. A left hemiparesis was present after this seizure and has persisted to the present time. Prior to this referral, the patient has been followed at the Sister Kenney Institute primarily for physical therapy of his left hemiparesis.

At age 13 the patient began experiencing grand-mal seizures. During the next two years he had between 10 and 20 grand-mal convulsions. An adjustment of his anticonvulsant medications from dilantin 100 mg. t.i.d. and phenobarbital 60 mg. b.i.d. to dilantin 100 mg. t. i. d. and mebaral 100 mg. q.i.d. resulted in complete control of his seizures. He has remained seizure-free to the present time.

Physically the patient still presents a problem in that his left hemiparesis has produced mild but significant contractures in his left upper and lower extremities. In addition, the question also arises about his future education, his occupation, and what recommendations and encouragement should be given him.

Neurological Evaluation

Dr. Robert Soll*:

Neurologically this patient presents with a mild left hemiparesis accompanied by hyperreflexia of both the left arm and the left leg and a Babinski sign in the left foot. The fact that there is no significant alteration of his sensation on the left side indicates that the neurological deficit is confined almost completely to the motor pathways. X-rays of the skull reveal no evidence of asymmetry which might have been expected if significant atrophy of the right hemisphere had been present since an early age. A recent electroencephalogram was interpreted as being moderately abnormal with multifocal slow spikes and waves in the frontal, temporal and mid-temporal regions on the right; however, there was

Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatric conferences are held every Wednesday from 1:00 to 3:00 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Charles Branthaver and Dr. Edward Defoe in Pediatrics, and Dr. Robert Soll, in Adult Neurology. Held on January 19, 1967.

*Department of Neurology, University of Minnesota Hospitals.

Continued

diffuse slowing bilaterally. This record showed no significant change from a previous record taken in May 1965. It is anticipated that the patient will have to continue on anticonvulsant medication indefinitely. It would also be wise to discuss the general nature of seizures and their causes with the patient in order that he have a thorough understanding of his own condition. There are several excellent pamphlets that are available for patients to read that could be used to supplement this discussion.¹

Etiologically no cause was ever found to account for this patient's convulsive disorder and left hemiparesis. He apparently had had a perfectly normal birth without any complications and there has been no history of any serious injuries prior to the onset of his first seizure at age 18 months. In view of the rather abrupt appearance of a convulsion during a febrile episode, leaving as a sequela a left hemiparesis, one might speculate that the patient probably had an acute cerebritis which produced its most severe damage in his right cerebral hemisphere.

Physical Medicine Evaluation

Dr. Frank Meelhuysen*:

As the patient walks, he is unable to place his left heel down on the floor. This is the result of shortening of the triceps surae muscle on the left. If he attempts to stand with his left heel on the floor he has to lean forward with the upper half of his body to keep his balance. Passive dorsiflexion of the left foot with the knee extended is limited to 110°, representing a 20° loss of mobility. Attempting a similar maneuver with the knee flexed is limited to approximately 100°. Thus a contracture is present in both the gastrocnemius and the soleus, although most of the spasticity is in the latter.

Passive prolonged stretching of the calf musculature in time may accomplish adequate lengthening of the muscle; however, a more practical approach would be a tenotomy of the left Achilles tendon. This can be done quickly and would permit almost immediate ambulation of the patient. This procedure should be supplemented by fitting the patient with a short leg brace having an ankle stop at 90° which can serve as a "built-in" gastrocnemius muscle at the push-off phase of the gait cycle. It could also be used as a night splint in order to maintain the foot in a dorsiflexed position, thus maintaining the increased range of motions of the ankle. I would recommend an orthopedic consultation concerning the suggested tenotomy.

A further suggestion would be a reduction of the spasticity in the gastrocnemius and the soleus muscles of the left leg by means of motor point blocks using phenol solution. As you know this does not permanently reduce the spasticity but will relax the muscles for three to six months and permit passive stretching of those muscles more readily and effectively.

Moderate spasticity is also present in the left forearm flexors, both in the wrist and finger flexors. Very likely, continued passive stretching of these muscles should be sufficient to maintain their functional length. This can be accomplished by having the patient place his left hand with fingers and palm flat on a table, and keeping his elbow extended. He then leans forward causing the wrist to be forced into dorsiflexion. If passive stretching by this means proves to be insufficient, motor point blocks in some of the above mentioned flexors may also be helpful in facilitating the stretching.

*Assistant Professor, Physical Medicine and Rehabilitation, University of Minnesota Hospitals.

Psychological Evaluation**Dr. John Brantner^{*}:**

The patient has an average intelligence as indicated by a full scale WAIS intelligence quotient of 94. Since this is actually at the bottom of the average range, one would anticipate that he would do roughly C work in high school. On the other hand, he would have an extremely difficult time in most college courses. His level of abstract verbal ability is low. The Porteus Maze placed him at 100.

In regard to his personality, he is well controlled with no tendency toward impulsiveness or carelessness. Indications for brain damage are at best borderline and probably not significant. We have obtained two multiphasics on him within four days, which were almost identical except for a rather marked change in the level of psychic energy. This might indicate that he is sensitive to fatigue or possibly to his drugs. Otherwise the Minnesota Multiphasic Inventory showed him to be cheerful, optimistic, and reasonably socially oriented with no evidence of depression, anxiety, or concern over his physical condition. On the other hand, his level of social maturity is somewhat low. Interestingly, he was given the high school form of sentence completion test which has forty items in it. His answers included the word "girl" in 25 instances. This suggests that he is very concerned at the present time with his image of himself as a successful heterosexual, masculine kind of person.

Vocational plans are not going to be easy with this boy. His physical handicap probably will not be too difficult for him as far as his being a printer is concerned, since he is intellectually capable of doing this kind of work. Also according to his interest pattern, this is the type of work he should be directed into. In the interest test he clearly rejects the scientific area and is not greatly interested in developing verbal skills. Outdoor activities or active vocations such as printing would be good for him because his interest pattern definitely is that of a worker rather than an executive. It would be unfortunate for this patient to be encouraged to go to college, since his intelligence level is in the low average and his interest pattern does not fit well with college level work.

Social Service Evaluation**Miss Helen Kretchmer^{**}:**

The patient's counselor said the patient was a "Huckleberry-Finn" type of person at an earlier age but that he has changed recently. The patient had a summer job in a YMCA work training project before he entered senior high school. He apparently worked harder than the 14 other boys in this project which was provided for boys who had an inadequate home situation. His counselor was not certain why the patient had been chosen, although it may have been because he did not have a father at home. Tests at the YMCA revealed that the patient was limited in his reading skills but very capable when doing active work. In school his grades have been acceptable during this past year and he has been active in sports and Junior Achievement. His home-room teacher stated that he is a striver and that he tries to do the best he can despite his handicap. Although his pace is rather slow, he is dependable, quiet, and gets along well with others. According to his teacher, he apparently makes occasional gross mistakes, and his counselor noted that he is extremely poor in reading skills.

^{*}Associate Professor, Clinical Psychology, University of Minnesota Hospitals.

^{**}Supervisor, Social Service Department, University of Minnesota Hospitals.

Continued

The patient is an only child whose father has been out of the home for a long time. His stepfather has been gone since the patient was 12 years old. The grandparents are young, ages 62 and 61 years of age, and the patient has an uncle, age 22, who was reared as his brother. They all live together in an apartment building. The mother feels that the patient does very well in school and does not expect more of him than he is capable of doing. She works from 10:30 in the morning until 7:00 at night. The only problem with which the mother is concerned is her feeling that her son is "high strung." He gets very angry and upset on occasion when she tries to talk to him. Apparently he acts as though she knows nothing. This is beyond what she would ordinarily expect of a boy his age and she worries that it may lead to a more serious problem later. She would like some counselling in this regard.

Recommendations of the Community Service Conference

1. Avoid encouragement into advanced education or advanced training and rather promote the patient's interest in a vocational training area.
2. Continue seizure medications indefinitely and discuss the general nature of convulsive disorders with him in order to increase his understanding of his condition.
3. Consult orthopedics concerning a left Achilles tenotomy in order to lengthen his contractures; subsequently fit the patient with a short leg brace if a tenotomy is done.
4. Reduce the spasticity in the left gastrocnemius by motor point blocks.
5. Consider motor point blocks in the left forearm flexors if passive stretching proves to be insufficient in the upper extremity.
6. Send a summary to the patient's eleventh grade counselor.

Robert W. Soll, M.D.
University of Minnesota Hospitals

Participating in the conference were: Miss Helen Kretchmer, Supervisor, Social Service Department; Dr. John Brantner, Associate Professor, Clinical Psychology; Mr. David Osborn, Clinical Psychology Trainee; Dr. Frank Meelhuysen, Assistant Professor, Physical Medicine and Rehabilitation, and Dr. Robert Soll, Department of Neurology.

Mr. Barzun Comments

Catastrophic Remodeling

"With the first successful appendectomy in 1890, the abdominal cavity became the playground of the surgeon." A surgeon wrote this in all seriousness and self-satisfaction and his spirit lives on. Every convention discloses a busy group of specialists who discuss new and better ways of removing your liver without injuring your lights, and who deplore at the same time that half their cases are either inoperable or too far gone to yield anything but a technical victory to the operator. Lately one elderly man was completely remodeled inside at a cost of eight anesthetics, twenty-two hours total operating time, and a fee of \$20,450.

Is it possible—and I ask out of complete ignorance and humility—is it possible that if the patient had been under the lifelong care of one physician who knew his history, occupation, and mode of life, who stood in some permanent relation to him and was interested in his well-being, is it possible that this marathon with the scalpel could have been forestalled?

Jacques Barzun: *When the Doctor Is a Pill (In God's Country and Mine)* 1954

Grand Rounds

Electrical Conversion of Cardiac Arrhythmias *

NEIL HOFFMAN, M.D.
Medical Resident

THE USE OF electric current for terminating cardiac arrhythmias was first credited to Prevost and Battelli in 1899.¹ They applied strong electric currents to the exposed hearts of dogs to stop ventricular fibrillation. Little attention was given the procedure, however, until 1933 when Kouwenhoven reported that AC current applied directly to the exposed heart could terminate ventricular fibrillation.² This had limited clinical usefulness, however, until 1960 when Kouwenhoven demonstrated that, in the arrested heart, pressure over the lower sternum would maintain adequate blood flow to vital organs.³ This concept extended the time available for the effective use of countershock in ventricular fibrillation. In 1962, Zoll demonstrated that electric current applied to the intact chest wall was effective in abolishing certain arrhythmias, particularly in terminating ventricular fibrillation.⁴ Actually Zoll first used electric countershock in 1956 when he applied the current transthoracically in four patients with various arrhythmias, reporting one survivor.^{5,35} Beck,³⁴ in 1947, reported the first successful use of countershock with open-heart massage, a case in which the patient made a complete recovery.

Vulnerable Period

In 1940, Wiggers showed that an electrical shock, when applied to the intact heart, could cause the heart to go into ventricular fibrillation.⁶ He demonstrated that even a very small shock to a localized area of myocardium, when timed to the ascending limb of the EKG T wave, would cause most dogs' hearts to go into ventricular fibrillation. This time sequence in the cardiac cycle has been called the vulnerable period.

The vulnerable period for ventricular arrhythmias in man measures 30 milliseconds and just precedes the apex of the T wave. A similar vulnerable period has been noted for atrial arrhythmias and has been shown to occur during the down slope of the R wave. Vulnerable periods have been identified in other

Continued

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, Minneapolis, January 3, 1967.

mammalian hearts; all have the same duration and location.¹

In 1940, Wiggers also postulated that direct current would be better than alternating current because one could time a single shock to occur at the beginning of the cardiac cycle, and since the current would be stored in a capacitor, the variations in current strength available in the AC input line would be avoided.⁶

To compare the effectiveness of AC versus DC current, Lown in 1962 studied 55 dogs in sinus rhythm. He then applied equal voltage across an intact chest to these dogs and did not time the discharge to fall within any portion of the cardiac cycle. He showed that random shock would produce ventricular fibrillation in two percent of normal dogs. Of 20 dogs that received AC shocks seven died, while in 35 dogs with similar DC voltage there were no deaths.⁷ The fact that ventricular fibrillation occurred in two percent of normal dogs limited the clinical usefulness of this tool to humans. Lown then showed that by synchronizing the release of the discharge to fall during a safe part of the cardiac cycle, ventricular fibrillation could be avoided.^{8,9}

Prior to "cardioversion", drugs were the mainstay in the treatment of cardiac arrhythmias. The use of drugs presented many problems. The effective or toxic dose in an individual patient could not be predicted. Since the dosage varies, it is necessary to titrate safe increments of the drug at frequent intervals. This may be tedious and time-consuming to the physician, requiring constant monitoring.^{1,9,10,11,12,13,14} Because these drugs are time-consuming and carry a two-percent mortality rate, the simpler method of cardioversion, as popularized by Lown, became the accepted one.

Theoretical Basis for Cardioversion

Cardioversion for electrical arrhythmias is based on the following propositions:

The forces that initiate ventricular fibrillation are generally transient, but once started seem to be self-sustaining.

The sino-atrial node has the highest rhythmicity, and when an abnormal rhythm is momentarily stopped, the S-A node will assume its normal rate as a pacemaker.

Depolarization of the entire heart can be done across an intact chest.

Cardioverter^{1,7,9}

The cardioverter as popularized by Lown is composed of four separate parts:

D. C. Defibrillator

This has a specific wave form, calibrated in watt seconds, with enough energy to depolarize the heart across an intact chest. This delivers a monophasic pulse of 2.5 millisecond. The machine is calibrated from 0-400 watt seconds.

Synchronizer

This permits the discharge at a preselected phase in the cardiac cycle, using the R wave as a trigger point to discharge the electric shock, thus avoiding the vulnerable period.

Cardiometer

This allows a permanent ECG to be taken and provides an R wave as refer-

ence for the synchronizer. There is also an ECG reversal switch to artificially make an S wave appear as an R wave.

Cardioscope

This provides an oscilloscope for monitoring purposes.

Beneficial Effects of Normal Sinus Rhythm

Most studies in comparing atrial fibrillation to sinus rhythm show definite improvement in cardiac performance when sinus rhythm is restored. *Cardiac output increases, ventricular rate with exercise decreases, and stroke volume increases.*^{15,16,17,36} Rodman¹⁸ studied 36 patients with cardiac catheterization before and five to seven days after restoration of sinus rhythm. He showed that stroke volume was increased from 35 millimeters to 77 millimeters (45%) with no essential change in heart rate. This emphasizes that the hemodynamic benefits attained with restoration of sinus rhythm cannot be attributed entirely to reduction of heart rate. Knox showed that even in well controlled atrial fibrillation the rise in left ventricular pressure is significantly higher in patients with atrial fibrillation than in those with sinus rhythm. It has also been established that patients with atrial fibrillation with no other evidence of heart disease may develop cardiac dilatation and failure.¹⁹

Indications for Cardioversion

Patients Who Should Undergo Cardioversion^{11,18,20,21}

1. Patients who are fibrillating and have a history of systemic emboli. As this is a prime indication, every effort should be done to maintain sinus rhythm.
2. Patients in congestive heart failure who are in atrial fibrillation and still have significant cardiac decompensation. Here, repeated reversions over the course of years may be helpful.
3. Patients with cardiac decompensation after an acute episode, e.g., acute myocardial infarction, where a supraventricular arrhythmia may be life threatening. Many investigators feel that cardioversion in these poor-risk patients without anesthesia is better than prolonged ineffective medical management.
4. Patients with ventricular tachycardia.
5. Patients with ventricular fibrillation.

Relative Contraindications because of Questionable Value^{10,20}

1. Slow atrial fibrillation without digitalis. This type of atrial fibrillation is generally associated with ischemic heart disease.
2. Intolerance to anti-arrhythmic drugs. Even though electrical conversion will restore sinus rhythm an anti-arrhythmic drug is generally necessary for maintaining this rhythm. One of our patients (#6) was found to be intolerant to Pronestyl and quinidine; after her second cardioversion she is being maintained on dilantin.
3. Previous cardioversion without improvement and early recurrence.
4. Benign atrial fibrillation of long duration. Data in this group fail to show any hemodynamic benefit in restoration of sinus rhythm.²² Oram reported some

Continued

benefit²³; but since the morbidity is low and these patients are generally asymptomatic the indications for cardioversion are equivocal.

Relative Contraindications—Defer to Later Date^{8,20,25}

1. Recent onset of supraventricular tachycardia. Most paroxysmal arrhythmias will revert within one week; therefore Morris²⁰ suggests drug therapy for one week.
2. Candidates for cardiac surgery who are stable.
3. Postoperative cardiac patients. Experience here has shown that the recurrence rate is less if one waits until the postoperative convalescence is nearly complete before attempting to restore sinus rhythm.^{20,21,24}
4. Patients with atrial fibrillation, secondary to hyperthyroidism (over 50 percent) will revert to sinus rhythm with the return of a euthyroid state.
5. Patients with recent systemic emboli. Here an eight-week period of anticoagulation is advised to give the mural thrombosis time to adhere and prevent dislodgment at the time of cardioversion.

Absolute Contraindications to Cardioversion^{17,20}

1. Digitalis intoxication. Electrical reversion of these arrhythmias results in a higher mortality rate because of an irritable myocardium that may produce multifocal PVC's or Stokes-Adams attacks.
2. Complete heart block. Here restoration of sinus rhythm will not alter the hemodynamic effects. Also this type of individual tolerates anesthesia poorly, and the risk from embolization is low.
3. Angina, relieved by the onset of atrial fibrillation.
4. Recurrent episodes of supraventricular tachycardia. This may be so uncomfortable that it seems best to leave these patients in atrial fibrillation.
5. Sinus tachycardia.

Technique of Cardioversion (Table 1)

Cardioversion is generally done using the Lown cardioverter in the following manner. Digitalis should be discontinued for 48 to 72 hours and an attempt made to control congestive heart failure with bedrest, diuretics, and a low salt diet. Quinidine therapy in doses of 1.2 grams to 1.6 grams should be given in individual doses 24 hours prior to cardioversion. The patient is not allowed food or fluids orally the day of cardioversion, except for the anti-arrhythmic agent. If general anesthesia is to be used, atropine just prior to induction helps control secretions.

The patient is then connected to the cardioverter with the operations switch turned to the monitor position. An appropriate ECG lead is decided upon so that a suitable R wave can be used as a trigger. The height of this wave can be artificially increased by using the gain control. If an S wave is to be used, the ECG reversal switch must be used, so that this negative S wave will appear on the screen as a positive deflection. The operations switch is then turned to the cardioverter position. At this time the signal light will blink each time the R wave has enough magnitude to fire the machine. This is an automatic synchronizer built into the machine. The synchronizer will trigger the machine so that the shock will fall 0.07 seconds after the R wave. Thus the entire shock

is delivered away from the vulnerable period, which for ventricular arrhythmias is at the apex of the T wave. There is a small danger of precipitating atrial arrhythmias, but in Lown's large series only two episodes of atrial fibrillation occurred, both responding to reconversion.²⁶

The proper voltage is then selected. Generally 100 watt seconds is used as the initial voltage. The paddles are well lubricated and placed in the left infra-scapular position posteriorly, and in the fourth right interspace (V_1 pos.) anteriorly. The discharge button is then depressed and held until the shock is obtained. The voltage is then turned to zero reading and the reset button depressed. This will empty the capacitor of any remaining charge. If the patient remains in an undesired arrhythmia the energy level is increased by increments of 50 watt seconds until the maximum level of 400 watt seconds is reached. If the patient does not convert with a voltage of 400 watt seconds, it is suggested the procedure be terminated.

Use of Anesthesia

Recently the need for anesthesia has been questioned. Several investigators show series of repeated cardioversion without anesthesia.^{12,14,17,27,28} Lown suggests that voltages of 100 watt seconds or less are well tolerated by the patients; however, anesthesia does seem to be the procedure of choice. Anectine and other muscle relaxants seem to potentiate the action of quinidine and therefore should not be used.

Anticoagulants

The question of anticoagulants is not fully resolved. No series can show an

TABLE I
Summary of Technique of Cardioversion

SUMMARY OF TECHNIQUE OF CARDIOVERSION	
1.	Control of congestive heart failure.
2.	Stop digitalis therapy 48 to 72 hours prior to cardioversion.
3.	Anti-arrhythmic drug: usually quinidine 300 to 400 mg. q6h. p. o.
4.	Nothing per mouth for 12 hours prior to procedure except for oral anti-arrhythmic drug.
5.	No specific premedication necessary.
	a. Atropine, 0.6 mg., parenterally just before cardioversion if anesthesia is to be used.
6.	Anesthesia, optional; brevital, penethal.
7.	Paddle placement.
	a. Anterior fourth interspace just to the right of the sternum (V_1 position on ECG).
	b. Posterior at the left infrascapular area.
8.	Find representative ECG lead. Lown cardioverter has ECG reversal switch so that either R or S wave of ECG can trigger charge.
9.	Turn switch from monitor to cardioverter.
10.	Set desired voltage (usually start with 100 watt seconds).
11.	Press discharge button and keep depressed until shock is delivered.
12.	Turn intensity switch to zero and press reset button; now reading on voltage scale should read zero.
13.	Resume anti-arrhythmic agent.
14.	Resume digitalis in 24 hours if necessary.

Continued

GRAND ROUNDS

advantage for using them.^{1,10,14,17,26,27,28} Morris reviewed 784 cases of cardioversion and found systemic emboli in 1.1 percent. It is significant that only one appeared immediately after cardioversion. Generally they occur two to 10 days after the procedure. He advises anticoagulation only if there is a history of previous embolism and suggests their continuance for two to three weeks following cardioversion.²⁰

Complications

The most common complications following cardioversion are transient arrhythmias. These are enhanced by digitalis toxicity. Killip¹⁰ reports one case of ventricular fibrillation produced when an artifact triggered the shock.

Cardioversion is considered safe. Kong²⁹ reported one patient who underwent 140 D.C. shocks within a 69-hour period. This patient died but at autopsy there was no evidence of myocardial injury. In over 1,200 reported cases there was only one ECG compatible with injury, but in that case the serum enzymes were normal.³⁰ In the absence of digitalis toxicity Morris²⁰ reports in 784 episodes an incidence of ventricular arrhythmias of 0.5 percent, with no mortality.

Results

The reported results in conversion of atrial fibrillation to normal sinus rhythm run 91 to 95 percent, and for conversion of atrial flutter to sinus rhythm about 94 to 100 percent.^{8,12,20,26,31,32,33} Generally long-term follow-up of these patients has been disappointing. Only about 50 to 60 percent are still in sinus rhythm at the end of nine months.^{10,11,20,28} Factors that seem helpful in determining who will remain in sinus rhythm are: (1) The etiology of the arrhythmia. (2) The duration of the arrhythmia. (3) The functional classification of the patient at the time of cardioversion.

Patients with rheumatic heart disease, with lesions other than mitral stenosis, and those with ischemic heart disease and hypertensive heart disease frequently revert to atrial fibrillation. Patients with mitral stenosis seem to show a higher percentage of maintaining sinus rhythm. Also noted is the fact that if atrial fibrillation is present for less than one year, there is a greater chance for continuation of sinus rhythm. The presence of functional class III or IV in cardiac patients with fibrillation does not generally maintain sinus rhythm.^{1,9,20,27}

Hennepin County General Hospital Series (Table 2)

This series is not a complete review of our experience. From November, 1965, to December, 1966, our series includes nine patients, with one patient undergoing conversion on two separate occasions. Six of our nine patients were thought to have valvular disease, one with isolated aortic stenosis. One patient remained in sinus rhythm for only one month, stopped taking his medications, and was thought too unreliable for reconversion. Another patient (#7) had rheumatic heart disease and no detectable mitral lesion. He also reconverted to atrial fibrillation in six weeks. The other seven patients were followed from a period of one month to 13 months and have remained in sinus rhythm. The average time duration in our patients from onset of fibrillation to cardioversion was less than 12 months, but one patient was fibrillating for at least three years before conversion. He reverted to atrial fibrillation in one month. One patient had a mitral valve replacement and was converted two and one-half months after surgery. All our patients are on maintenance quinidine therapy averaging

ELECTRICAL CONVERSION OF CARDIAC ARRHYTHMIAS

1.2 grams per day except for patient #6, who was found to be intolerant to quinidine and pronestyl and is being satisfactorily maintained on dilantin.

TABLE 2
Experience at Hennepin County General Hospital

Patient	Age	Onset of Atrial Fibrillation	Date of Cardioversion	Follow-up	Anticoagulants Used	Sinus Rhythm
1. C. J.	76	11/62	4/65	1 mo.	No	No
2. H. M.	54	?	11/66	2 mo.	Yes	Yes
3. S. B.	62	7/65	1/66	12 mo.	No	Yes
4. J. S.	60	?	10/66	3 mo.	No	Yes
5. R. L.	60's	7/65	4/66	9 mo.	No	Yes
6. M. F.	60	?	11/65	9 mo.	Yes	No
			(2-1/2 mo. post mitral valve)			
		8/66	8/66	5 mo.	Yes	Yes
		(Now on dilantin)				
7. J. B.	61	?	11/65	1 mo.	Yes	No
8. W. M.	52	4/66	12/66	1 mo.	Yes	Yes
9. M. H.	54	?	12/66	2 wk.	No	No

Our success rate for immediate conversion was 100 percent. One patient required 250 watt seconds, the others converting generally after one shock at 100 watt seconds. Our follow-up period averages six and one-half months per patient and shows 66 percent of our patients to be in sinus rhythm. Three of our patients were anticoagulated by no specific criteria and no case of embolism was noted in our series. All of our patients had general anesthesia, and none reported undue chest discomfort or erythema following the procedure. When serum enzyme levels were obtained following cardioversion they were normal. Transient arrhythmias were noted, but no sign of myocardial damage was seen in follow-up ECG's.

Summary

Generally the initial conversion success rate is excellent with most series reporting 50 to 60 percent remaining in sinus rhythm for nine to 12 months. Anticoagulants were found not to alter morbidity or mortality. They are used generally for "high risk" patients, those with a previous history of embolic phenomena. Embolization has been reported at from 0.6 percent to two percent with no relationship to anticoagulants. Digitalis toxicity greatly enhances the morbidity of cardioversion. The most common complication is transient arrhythmias. Cardioversion seems to be the method of choice for conversion of atrial fibrillation and flutter.

I am suffering from my old complaint, the hay-fever. I melt away in nasal and lachrymal profluvia. My remedies are warm pediluvium, cathartics, topical application of a watery solution of opium to eyes, ears, and the interior of the nostrils.

—Sydney Smith

A large, dark, grainy microscopic image showing numerous spermatozoa with long, wavy tails. In the upper left corner, there is a smaller, rectangular inset showing a different microscopic view, possibly of cervical mucus or a different type of cell.

New view of an oral contraceptive at work

Although suppression of ovulation remains the primary mode of action of oral contraceptives, newer knowledge indicates that products like Norinyl-1 — a combination of both low-dosage progestogen and estrogen for the full treatment cycle — may provide multiple action that helps explain their unexcelled record of contraceptive effectiveness. This report explores the possible secondary protective mechanisms offered by combined hormonal administration.

Accumulating evidence has indicated that sparse, highly viscous cervical mucus has a possible adverse effect on the motility and survival of spermatozoa.

The estrogen-opposing progestational ingredient of Norinyl-1 (norethindrone 1 mg. with mestranol 0.05 mg.) changes the usual mid-cycle picture of a thin, watery cervical mucus. The result — a built-in barrier that appears to inhibit sperm from reaching the ovum should one be released. The inset in the adjoining photograph shows immobile spermatozoa as they appear in cervical mucus taken from a patient treated with Norinyl-1.

How the estrogen-opposing action of Norinyl-1 creates cervical mucus that may be hostile to sperm penetration

Normally, estrogen activity during the fertile midcycle stimulates the production of a profuse and watery cervical mucus that permits maximum sperm motility and promotes penetration.

But what happens when Norinyl-1 is administered? Its potent progestogen, norethindrone, opposes estrogen stimulation of cervical mucus. Consequently, the amount of mucus decreases and its viscosity increases. This results in a sparse but thick mucus barrier that appears to diminish the vitality of the sperm and to impair its powers of penetration.

The role of viscous cervical mucus as a secondary action of Norinyl-1

In a report on 89 patients taking this medication,* cervical mucus obtained from cycle day 5 to cycle day 29 appeared scant and thick and exhibited little or no Spinnbarkeit.

In the opinion of this investigator, the effect on cervical mucus may be sufficient to prevent conception.

*Cohen, M. R.: Symposium: Mechanisms of Action of Low Dosage Oral Contraceptive, Yale University Medical Center, New Haven, Conn., April 6, 1967.

Normal cervical mucus at midcycle in untreated patient is known to permit sperm motility... promote sperm penetration.

Cervical mucus is thin and watery with a stretchability (Spinnbarkeit) of 15 to 20 cm.

Thin, watery mucus crystallizes into this well-defined, fernlike pattern within a minute.

Spermatozoa appear healthy, are active and freemoving.

Viscous cervical mucus at midcycle produced by Norinyl-1 appears to impair sperm vitality... inhibit penetration.

Cervical mucus is scanty, thick and viscous. Spinnbarkeit is 1 cm. or less.

In thick, viscous cervical mucus the fern pattern is poorly defined or absent.

Immobile spermatozoa as they appear in cervical mucus taken from a patient treated with Norinyl-1.

How Norinyl-1 alters normal endometrial responses— another possible protective mechanism

Let us suppose that an ovum is released—as occurs in an occasional, rare case—and somehow a sperm succeeds in penetrating the cervical mucus barrier. Should this come about, one additional action of Norinyl-1 may protect the patient from unwanted pregnancy. The theory is that progestogen intake makes endometrial tissue unreceptive to implantation.

Endometrium of
untreated patient

Normally, the endometrium progresses through a proliferative phase stimulated by estrogen and a secretory phase stimulated by progesterone. During the secretory phase the endometrium is receptive to the fertilized ovum.

Endometrium produced
by Norinyl-1

When Norinyl-1 is administered its progestogen component—norethindrone—accelerates the secretory phase and suppresses glandular and vascular development.

effective fertility control
on half the previous dosage
maintains ratio
of the established
norethindrone/mestranol
combination
lower cost

new Norinyl-1[®]

(norethindrone 1mg. $\bar{c}$ mestranol 0.05mg.) tablets

Reduction of oral contraceptive dosage to lowest effective levels has become a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now available in a new strength in which both norethindrone and mestranol are reduced 50 percent. Studies show that Norinyl-1 achieves fertility control with only 1.05 mg. of combined progestogen and estrogen per tablet.

Norethindrone was first reported for use as a progestational agent in human beings in 1955. Norethindrone 2 mg. with mestranol 0.1 mg., as an oral contraceptive, is currently in use by over 2,000,000 women. Clinical experience now establishes that Norinyl-1 also amply meets the criteria of reliability and safety.*

*Symposium on Low-Dosage Oral Contraception, Palo Alto, Calif., July 15, 1965.

PRESCRIBING INFORMATION

Contraindications: 1. Patients with thrombophlebitis or with a history of thrombophlebitis or pulmonary embolism. 2. Liver dysfunction or disease. 3. Patients with known or suspected carcinoma of the breast or genital organs. 4. Undiagnosed vaginal bleeding.

Warnings: 1. Discontinue medication pending examination if there is sudden partial or complete loss of vision or if there is a sudden onset of proptosis, diplopia, or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. 2. Since the safety of Norinyl-1 in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. 3. Detectable amounts of the active ingredients in oral contraceptives have been identified in the milk of mothers receiving these drugs. The significance of this dose to the infant has not been determined.

Precautions: 1. The pretreatment physical examination should include special reference to breast and pelvic organs, as well as a Papanicolaou smear. 2. Endocrine and possibly liver function tests may be affected by treatment with Norinyl-1. Therefore, if such tests are abnormal in a patient taking Norinyl-1, it is recommended that they be repeated after the drug has been withdrawn for 2 months. 3. Under the influence of estrogen-progestogen preparations, preexisting uterine fibroids may increase in size. 4. Because these agents may cause some degree of fluid retention, conditions that may be influenced by this factor, such as epilepsy, migraine, asthma, cardiac, or renal dysfunction, require careful observation. 5. Although a cause and effect relationship has not been established, Norinyl-1 should be used with caution in patients with a history of cerebrovascular accident. 6. In relation to breakthrough bleeding, as in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are

indicated. 7. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. 8. Any possible influence of prolonged Norinyl-1 therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. 9. A decrease in glucose tolerance has been observed in a small percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Norinyl-1 therapy. 10. Because of the occasional occurrence of thrombophlebitis and pulmonary embolism in patients taking oral contraceptives, the physician should be alert to the earliest manifestations of the disease. A cause and effect relationship has not been demonstrated. 11. Because of the effects of estrogens on epiphyseal closure, Norinyl-1 should be used judiciously in young patients in whom bone growth is not complete. 12. The age of the patient constitutes no absolute limiting factor, although treatment with Norinyl-1 may mask the onset of the climacteric. 13. The pathologist should be advised of Norinyl-1 therapy when relevant specimens are submitted.

Side Effects: The following adverse reactions have been observed with varying incidence in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms, breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma, breast changes (tenderness, enlargement and secretion), loss of scalp hair, change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately postpartum, cholestatic jaundice, erythema multiforme, erythema nodosum, hemorrhagic eruption, migraine, rash (allergic), itching, rise in blood pressure in susceptible individuals, mental depression.

The following occurrences have been observed in users of oral contraceptives. A cause and effect relationship has not been established: thrombophlebitis, pulmonary embolism, neuroocular lesions.

The following laboratory results may be

altered by the use of oral contraceptives: increased bromsulphalein retention and other hepatic function tests, coagulation tests (increase in prothrombin, factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T₃ values), metapyrone test, pregnane-diol determination.

Other side effects reported to have occurred in association with use of this drug are dizziness, hirsutism, pains in legs, back, chest and abdomen, dysuria, drowsiness, vaginal discharge, libido increased and decreased, eruptions, hypermenorrhea, hypomenorrhea, increased appetite, G.U. infections, varicose veins, abdominal fullness, acne, headache, nervousness, allergies, blurred vision, pain in eyes, and itching in eyes. For complete clinical data, see package insert.

Dosage and Administration: 1. One tablet of Norinyl-1 is administered orally for 20 days beginning on day 5 of the menstrual cycle. (Count day 1 of the cycle as the first day of menstrual bleeding.) Repeat this dosage schedule for each cycle. 2. If no menstrual period occurs after a cycle of treatment (20 tablets) in which patient adhered to the schedule, the patient must be instructed to resume taking the Norinyl-1 tablets 7 days after the previous 20-day course was completed. For example, if the last pill of a previous cycle had been taken on a Sunday, then a new cycle of treatment should begin on the following Sunday. 3. In the postpartum woman, it is recommended that the first cycle of treatment should begin on day 5 of the first menstrual cycle. However, Norinyl-1 should not be administered during lactation.

Availability: Norinyl-1 (norethindrone 1 mg. with mestranol 0.05 mg.)—Dispensers of 20 and 60 and bottles of 250 tablets.

norethindrone — an original steroid from

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical

facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

Abstracts, Briefs and Commentaries

ACUTE APPENDICITIS IN INFANTS THIRTY-SIX MONTHS OF AGE OR YOUNGER

Acute appendicitis in infants three years old and younger is quite uncommon; yet the mortality rate for this age group (6.7%) was nearly three times that for the entire 6,915 cases of the disease seen between 1953-1963 at the Los Angeles County Hospital.

Of the 30 cases reviewed 76.6% were ruptured at the time of surgery. There were two deaths. The authors stress a careful abdominal examination in a quiet child in order to detect objective evidence for appendicitis. This often requires medication. The hypohydrated, toxic infant must be carefully prepared prior to surgery.

Five factors contributing to a delay in diagnosis are: (1) failure to consider the possibility of appendicitis; (2) a poor history; (3) the frequency of vomiting in extra-abdominal conditions in infants; (4) antibiotics masking the disease; (5) more rapid progression of the disease in infants than in adults, resulting in earlier perforation.

Minneapolis, Minnesota

Fields, Irving A., and Cole, Norman M.: Acute Appendicitis in Infants Thirty-Six Months of Age or Younger. Ten-Year Survey at the Los Angeles County Hospital. *Amer J Surg* p. 269, February, 1967.

DEFINITIVE SURGICAL THERAPY FOR PERFORATED PEPTIC ULCER A REVIEW OF FIFTY-TWO CONSECUTIVE CASES

Definitive surgery to correct the ulcer diathesis may be performed in the presence of acute perforation with no increase in risk over simple closure or elective surgery and with equally satisfactory results. Fifty-two consecutively operated cases (minus 2) with a mortality of 1.9% are the basis for this report.

The author has followed all of his patients from fifteen months to six years with an average of three years. There was an incidence of dumping in 4%. Comparisons are drawn between this series and other published reports.

There is insufficient data in this report to warrant the author's conclusions. The time interval between perforation and surgery has not been studied. This would seem to be mandatory in a fair comparison of series. How can one judge the adequacy of an acid-ablative procedure with such a short followup?

Such a fine series of surgical cases so expertly handled deserves a more critical analysis. The author's conclusions may be right.

In managing tense, anxious patients
here's one combination that makes sense:
your understanding counsel
and **Serax[®]**
(oxazepam) Wyeth

When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly (see Wyeth literature or PDR as well as "IN BRIEF" below).

IN BRIEF.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance. Safety for use in pregnancy has not been established.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds, not established.

Side Effects: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leucopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age.

These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam.

Philadelphia, Pa.

9500 miles from Danang, Americans are fighting another enemy.

Inflation is a threat to every family's paycheck . . . to the strength of our nation itself. And while other Americans are engaged in the fight for freedom half way around the world, we must be increasingly alert to the dangers of inflation here at home.

American businessmen can help maintain a stable economy and curtail inflationary pressures through the Payroll Savings Plan for United States Savings Bonds. Money invested in Savings Bonds is actually an investment in the United States. It results in more effective

management of the public debt, maintains the value of the dollar and provides a firm base for family security.

In your plant or office, you can initiate and promote this program for systematic savings. Complete information is available from your State Savings Bonds Director or by writing the Treasury Department, United States Savings Bonds Division, Washington, D.C. 20226.

in your plant . . . promote the PAYROLL SAVINGS PLAN for U.S. Savings Bonds

The U S. Government does not pay for this advertisement. It is presented as a public service in cooperation with the Treasury Department and The Advertising Council.

Business is business.

Says who? Says too many people.

You've probably heard it yourself many times.
It's used to justify almost *anything*.

But how many times have you ever questioned this attitude or raised your voice in protest? An idea like this takes root just because not enough people do anything to stop it.

If you have ever asked yourself "Why doesn't someone do something about it?" you're talking to the right person. You.

It won't be easy. Sometimes you'll need encouragement. The kind you'll find in your place of worship.

Here you'll discover you're not alone. That, in itself, can give you the strength to say "Says who?" once in a while when it needs to be said.

Religion in American Life

Published as a public service in cooperation with The Advertising Council

Annual Meeting

Presidential Address - 1967*

Mr. Speaker, members of the House of Delegates, and Guests: I come before you today with a plea for patience such as you have never had to demonstrate in times previous. This past year has seen a start of a system of medical practice which the world has never seen attempted. There are many countries who have tried the well known system of government taking over the control of medicine lock, stock and barrel. We know that these systems have not worked in the public or professional interest, that is, we know that medical care has deteriorated in many ways under such a system, certainly with great loss of freedom to practice, such as we know it to be in our own country.

Government Interest in Medicine

We are attempting a great experiment, wherein government is seeking to purchase medical care from the private sector of medicine through third party arrangements, which have turned out to be many and varied, each state having tried to work out arrangements of its own, which makes each state's plan almost unique unto itself. This part is good, because out of all the conflagration that is going on now in all our efforts throughout the country to make it work, we are running into a host of hitherto unforeseen problems. This is why I plead with you as physicians, and I could just as well address myself to the public and government as well, to have great patience while we continue to work on these problems until they are satisfactorily solved. So many situations are new and without precedent that it is no wonder we have run into snags.

Bureaucracies

Let me make this point extremely clear. It is up to us to make it work, because, if we

don't, you can be sure that the government will then take over as they have done in England, and many other places.

We should not reject these new regulations out of hand, but make a courteous effort to work out our problems with all parties involved, The Federal Bureau of Family Affairs, Social Security Administration, our Public Welfare Department and the carriers. The carrier is acting as a buffer between government and medicine, and those who regard them in the same light as government are wrong. They should be regarded as part of the private sector of medicine. If the government has to take this entire effort over, it will get rid of the carriers, you can be sure.

Let me discuss some of our own experiences here in Minnesota during this past year. What have been our own unique problems?

Assignments

First of all, we were all asked to take assignments when it came to dealing with our welfare patients. This is the prime method, and really the only one, which is being used throughout the country as a method for collection from this particular group of patients. We were allowed to bill all other patients over 65 who had Medicare directly, collect from them, and they in turn could recover from the government that portion to which they were entitled by law, through the carrier arrangement. A high percentage of physicians throughout the country accepted this assignment method for Welfare Patients and apparently have found it to be satisfactory thus far.

Direct Billing

However, there is a sizable number of physicians here in Minnesota and in many other states who have refused to go along with this idea, and would not accept assignment. Through our own Task Force on Medicare, chaired so

*Given before the House of Delegates, May 14, 1967, Duluth, Minnesota.

Continued

ably by Dr. John Falls of Red Wing, we were able to obtain arrangements through the Department of Public Welfare to have the same direct billing method used for welfare patients. This meant that the welfare recipient had to either scrape the money together, pay the doctor, get a receipted bill and present this to his welfare board, so that they could pay their share, and also collect from the carrier the share to be paid by the Federal Government, or accept a promissory note so that a receipted bill could be given to the welfare patient. This proved to be a very awkward arrangement, but at least it was made possible by the efforts of Dr. Falls' Task Force.

This was not sufficient, however. Many physicians wished to continue to deal with their county welfare boards just as they had done for many years, and had developed reasonably satisfactory arrangements for the most part. This meant that they wanted to continue to bill their welfare departments directly, let the welfare people work out their own arrangements with the carriers for getting the Federal Governments share for them to utilize, and so simplify their own bookkeeping, feeling that the bookkeeping chore should properly be done by the welfare department, leaving them as free as possible to use their own time to the best advantage practicing medicine.

Changing Medical Economics

A striking change has occurred in medical economics in the past 20 years.

Paramedical Personnel

Most physicians are being called upon to see many more patients than they did years ago, and can't push themselves any harder. They have been able to do this by employing more so-called paramedical personnel, which has driven overhead up. Paper work has increased tremendously, but most physicians prefer to deal with their local people, and it is our obligation to assist them in doing this.

Legal Obstructions

It is at this point that we are now hung up. In order to do this, there must be amendments to our Title 18 and 19 laws. It could also be corrected by a rather simple change in the Fed-

eral law, and this is being worked on in Washington. That change in the Federal law would be to strike out the requirement for a receipted bill, and allow the physician to send his bill to both the county welfare department as well as the carrier. These two could then work out their own arrangements so that each could pay his share of the bill, and it could all be done without any use of assignment whatsoever.

Now there are many physicians in this state who do not agree that this assignment business holds the dangers or potential dangers that some seem to think, and would just as soon accept the assignment and go along with the prescribed method which the government is asking throughout the country. We have been asked by our own welfare people, why are the Minnesota physicians so different than any others in the country that they would refuse to accept assignment?

Private Practice vs. Government Employee

Let me give you some examples. For the greater part of my professional life I have been in the private practice of medicine, but now am an employee of the state government, yet you have honored me by electing me as your president without fear, I hope, that I would suddenly transfer my allegiance toward government medicine. It is obvious to me that service can be rendered from both positions, each respecting the other. You have given our Distinguished Service Medal to a long time state government employee, Dr. Robert N. Barr, Executive Secretary of our State Board of Health, who has steadfastly upheld the private sector of medicine. Dr. Valentine O'Malley has worked in the disability section of the Social Security Administration and has up-graded that governmental department, yet has maintained the closest relationship with private practitioners. One of our excellent recent presidents, Dr. Donald McCarthy came from a long full time post with the Veterans Administration to take that office. To me this indicates a trust in many physicians in government service at this level. We prefer to deal with physicians and non-physicians at these more local and state levels where we can know them, rather than with unknowns in Washington.

There is such marked disagreement over this taking of assignment, not only in Minnesota,

but elsewhere, that I think it is absolutely necessary for those of us in positions of medical leadership to try our best to uphold the rights of individual practicing physicians, and try to achieve that which they desire, if at all possible. This is exactly what we have been trying to do, and have gotten ourselves in many difficulties as a result.

The Right to Refuse

These physicians have billed their welfare boards, knowing that they could not be paid, and will not be paid until this matter can be settled legislatively, either by our own state legislature, or by Congress, as I have indicated. I also know that certain welfare boards have urged their physicians to change their minds and accept assignments, telling them that they could not be paid for any bill that is more than one year old, which may be true. The physicians are adamant, however, and there have been some rumors, and I would pray that they are no more than rumors, that these men would eventually refuse to render medical care to their welfare patients except for emergency care, because they were not getting paid. This would be utterly unthinkable, in my opinion, and would badly tarnish the image of the medical profession. It would not, in my opinion, solve the problem, but would, in fact, compound it, by placing us right in the same category as tradesmen, and take us out of the professional status entirely. Lest I be misinterpreted in making this statement about "tradesmen", let me say that these good people in our society have every right to do as they have done many times in improving their own lot by striking, but their work does not involve human life as directly as ours does, and therefore we are in a totally different situation. No matter what might happen in the economic affairs of any physician, I cannot believe that he should ever refuse to take care of a certain group of his patients purely on an economic basis. I hasten to add, however, that any physician in private practice may say "no" to the request for medical care from a single patient or his family for purely personal reasons. This has always been true. But to turn down the care of an entire group of his patients, such as those who have the misfortune to be on welfare would be utterly unprofessional, in my opinion, and would

be absolutely unethical. It would be labeled a STRIKE.

The Family Physician

I have spent a considerable amount of time in talking about this dilemma in which we find ourselves, because I think it deserved it. There are other matters which should be talked about too. One of the most urgent is the matter of Medical Manpower. As time has gone on, we all know that the Family Physician has become an increasingly scarcer entity. We must make the best use of the doctors in all fields, and this means that governmental agencies, in working with all of us on these new Medicare problems, *must free us from as much paper work as possible*, and allow us to spend as much of that time as possible in the care of the sick. Nor must we be forced to obtain more office help, which would in turn increase the cost of medical care.

The Internist

But to return to the topic of the Family Physician. Some Internists claim to be THAT individual, but how can he be, when he limits his work to adults, does no obstetrical work, does no surgery of any kind, and really is not equipped by training to serve the whole family as he ought to do to make good his claim. I know this will stir up a hornets nest, but this is to be expected. We must define what we are talking about.

The Pediatrician

Similarly, some Pediatricians also lay some claim to be the Family Physician. Truly, he cannot be this man either, by training or limitations by his Board.

The General Practitioner

This Family Physician of the future must be as much of a specialist as the surgeon, the internist, the pediatrician, the psychiatrist, and on through the list of specialties and subspecialties. In my opinion he must receive Board certification, and take his training accordingly. The medical educator must assist greatly in his development, as must those who plan the graduate training programs beyond medical school.

The American Academy of General Practice

Continued

is going through much soul searching these days, in an effort to redefine itself in light of the future. Also in my opinion there must be real exposure of the medical student to this man we presently call the General Practitioner, or Family Physician. The only way he can achieve sufficient stature in the eyes of the public and young person making up his mind on a career is to become a bona fide specialist, with University Faculty status, and probably have Chairs of Family Practice in the Medical Schools of the Country. Many types of experiments are going to go on, all over this land, to try to develop a greater interest in this field, and to make it a meaningful specialty, attractive to enough young people, so that over the next few years a far greater number will have the desire to enter into it.

The Medical School

Our own Medical School is in trouble. It needs more money for faculty, and is actually "faculty poor." About 70-80% of our University of Minnesota Medical School budget comes from Federal money in one form or another, and these research people and others who are not paid strictly as faculty members must be used to fill the gaps in the full time teaching staff.

Increase Enrollment

I am fully aware of the need for more physicians especially in the private practice sector. These numbers have been dwindling over the last 20 years, and I'm now talking about not only Family Physicians but many other segments of the private sector. Higher percentages are going into full time research, government service or industry, actually leaving fewer doctors per 1000 of population than we had a few years ago. Our own Medical School must expand as soon as possible to 200 students, then eventually to 250 as more facilities and teachers are available.

A Second Medical School

I'm in favor of a second medical school such as has been proposed for St. Paul, but only if it is affiliated with a major university and this could be done. If it would not so affiliate, it would be a weaker school at the very outset, and we might as well plan properly for this

second school or not at all. I'm not even sure if the State of Minnesota can afford two schools, and have their major support come from tax funds, but this may not be the plan for the second school. We certainly need to encourage our legislators to put more money into the one excellent school of medicine we have at the University of Minnesota and then see if we can afford to support a second school in a major fashion.

The Role of Private Hospitals and Practicing Physicians

The University of Minnesota Medical School is running low on patients and needs our help. Admittedly it is easier for those of us who practice outside the Twin City area to talk, and I can just hear my metropolitan colleagues saying to me, "If you lived and worked here, you'd whistle a different tune". Maybe so.

Referral of Private Patients

But something has to give, and it must of necessity start in the metropolitan area, but certainly should be shared by all of us, no matter where we practice in the state. I am talking now about the problem of seeing that the patient shortage for clinical work at the Medical School be unselfishly solved by deliberately developing as rapidly as possible both an adequate outpatient clinic, and in-hospital referral of surgical and medical patients for work by all the specialties represented therein. As I have said, the day of the so-called charity patient is about gone, hence we have no choice but to face that fact squarely, and work out a system to accomplish just this with the use of private patients. The Hennepin and Ramsey County Medical Societies together with the Twin Cities Hospitals are going to have to cooperate in this venture and lead the way toward its solution. There has always been a certain amount of friction between the Medical School Faculty and the practicing physician, but much of this is going to have to be buried and some real statesmanship shown on the parts of all those involved in order to solve the multitude of problems that lie ahead. We are all physicians, and, as the old saw goes, "if we don't hang together, we'll hang separately".

Conclusions

I don't pretend to have all the answers to these many questions, but do believe that there are reasonable answers to be found, without losing any more of our rights as private practicing physicians than we have already lost. The experiments being developed in Oklahoma and elsewhere will be watched with great interest. However, we don't need to wait for anyone else to develop an "ideal plan" because there may be no such thing.

Each medical school must develop its own plan, so we will hopefully wind-up with about 90 plans, each one unique unto itself because of its own necessarily different structure. But we must quit paying nothing but lip service to the idea of increasing the actual numbers of Family Physicians. While medical education may not have wittingly assisted in the great diversion of students into fields other than Family Practice, although each department must of necessity develop its own little empire, they must now actively plan and carry out some method such as I have suggested which will attract young people into this new specialty in ever increasing numbers until a better balance is reached. How long will this take? This cannot be answered very well until we see how successful the several medical schools are in the development of these new departments. Certainly it will be a minimum of four to eight years, even if a Chair of Family Practice could be started this year at the University of Minnesota, and we hope it will be.

Much has to be worked out in terms of further definition of this MEDICAL MAN of the future, the FAMILY PHYSICIAN. What shall his curriculum be? Shall the basic 4 year course remain

the same for all students, as it is now, or shall specialization begin with the very first year, or the second or the third? Much debate and thought must be given to this matter—AND NOW. Time is short, really, and no more must be wasted in debate about the necessity for such a program.

I hope we are all agreed on this. That these Family Doctors are needed now, so let's get on with it in any way that we can. Errors have been made and will continue to be made in finding the best method, but if the cooperation between private practice and University Faculty is developed to a greater degree, the job can be done without any question. We have many interested individuals and groups, eager to get started. One good beginning would be to have the University of Minnesota Medical Faculty put on a drive within their own numbers to join organized medicine. Too many of our faculty people have remained aloof from membership in Ramsey or Hennepin County Medical Societies as well as the Minnesota State Medical Association and AMA, and it has been a major deterrent, in my opinion, to closer ties and cooperation between the faculty and the private sector of medicine in our state.

Petty attitudes, jealousies and the like, which I have seen exhibited by both faculty and private medicine alike must be minimized. It cannot be stamped out entirely and have all be "sweetness and light", unfortunately. We have a remarkable opportunity here in Minnesota to lead the nation in this endeavor as we have done in times past in other efforts, so let us all accept this challenge and create a brighter future for medicine and the people we serve.

Charles G. Sheppard, M.D.
President

William III (1650-1702)

He was sickly and was continually worried about his health. He sometimes wrote to foreign physicians under an assumed name in order thus to obtain an unprejudiced opinion of his illness. The opinions were always unfavorable. He suffered with malaria and probably had tuberculosis, for he was for a long time tormented with a racking cough and at autopsy the left lung was found diseased. He also suffered with boils, and to treat them he dusted his skin with a mixture of flour and dried and powdered eyes of crabs. His death was hastened by a fall from his horse, from which he suffered a fracture of the right collar bone.*

Why Western Electric rewired its safety program to include training in defensive driving. And why you should too.

Last year, American industry lost over 22,000 trained employees killed in off-the-job traffic accidents. And 1½ billion dollars in lost time and production. But, hundreds of companies—big and small—are doing something about it. Like Western Electric. In the last two years, Western Electric trained 800 employees with the National Safety Council's Defensive Driving Course. And hundreds more are

signed up to take this complete course in new and tested concepts and techniques of defensive driving. You can do the same thing for the employees of your plant, office or facility. The National Safety Council will be glad to tell you how to set up the Defensive Driving Course in your company. And reduce traffic accidents among your employees *significantly*. Mail the coupon today.

In Memoriam

Men fear death, as if unquestionably the greatest evil, and yet no man knows that it may not be the greatest good. — W. Mitford

CARL G. SWENDSEEN, M.D.

Dr. Carl G. Swendseen, 72, Minneapolis eye, ear, nose and throat specialist, died April 9 in Pompano Beach, Florida. Born in St. James, Dr. Swendseen was a graduate of the University of Minnesota Medical School. He moved to Pompano Beach ten years ago.

He was a member of Khurum Lodge No. 112, AF & AM, Scottish Rite, Zuhrah Temple, the Swedish Hospital staff, Hennepin County Medical Society, American College of Surgeons and the American Medical Association. He was an associate member of the Minnesota State Medical Association.

He is survived by his wife and two sons.

ARTHUR C. KERKHOF, M.D.

Dr. Arthur C. Kerkhof, 63, Minneapolis heart specialist, died May 5, while attending a staff meeting at St. Barnabas Hospital. Born in Minneapolis, Dr. Kerkhof received his medical degree at the University of Minnesota.

Medical director for the Minneapolis Star and Tribune and Federal Cartridge Corporation, he was also a member of the National Board of Directors of the American Heart Association and chairman of the American Therapeutic Committee on Education. He was a past president of the Association of Minnesota Internists and the Minnesota Heart Association.

In addition, he was a member of the Hennepin County Medical Society, American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, a daughter and two sons.

CHRISTIAN A. FJELDSTAD, M.D.

Dr. Christian A. Fjeldstad, 83, Minneapolis ear, eyes and nose specialist, died April 21. He had practiced ophthalmology in Minneapolis for forty-seven years.

A former staff member of the University of Minnesota Hospitals and Fairview Hospital, Dr. Fjeldstad was a

member of the Hennepin County Medical Society and the American Medical Association. He was a 50 Club and Life Member of the Minnesota State Medical Association. In 1962 he received the Distinguished Service Award from Luther College, Decorah, Iowa.

He is survived by his wife, a daughter and a son.

HAROLD J. ROTHSCHILD, M.D.

Dr. Harold J. Rothschild, 83, St. Paul ear, eyes and nose specialist, died April 20. Born in St. Paul, Dr. Rothschild practiced ophthalmology in St. Paul for fifty-six years. He received his medical degree from the University of Minnesota Medical School.

A member of the staff at St. Josephs Hospital, Children's Hospital and St. John's Hospital, Dr. Rothschild was a member of the Minnesota Academy of Ophthalmology and Otolaryngology, American Academy of Ophthalmology and Otolaryngology, Ramsey County Medical Society and the American Medical Association. He was a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife.

FRANK J. ELIAS, M.D.

Dr. Frank J. Elias, 74, a physician in Duluth for half a century, died April 7, after a long illness. Before his retirement because of ill health five years ago, he had been associated as a partner in the Morgan Park Medical Center. A native of Racine, Wisconsin, and a graduate of the Marquette University Medical School, Dr. Elias came to Duluth to intern at St. Mary's Hospital and later was associated in practice with Dr. W. H. Magie.

He was a past president of the Minnesota State Medical Association, a past president of the St. Louis County Medical Society, a Minneapolis delegate to the American Medical Association, served as chief of staff of the St. Mary's Hospital, past president of the Interurban Medical Society of Duluth-Superior, and had been

Continued

IN MEMORIAM

a member of the state advisory board council on hospital construction from its inception. In 1954 he was given the Distinguished Service Medal of the Minnesota State Medical Association.

He was a fellow of the American College of Surgeons and a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Elias is survived by his wife, a daughter and a son.

WILLIAM THOMAS WALSH, M.D.

Dr. William T. Walsh, 56, Minneapolis physician, died April 6. He was a graduate of the University of Minnesota Medical School and was chief of staff at St. Barnabas Hospital in 1956.

Born in Minneapolis, Dr. Walsh was a member of the Hennepin County Medical Society, Minnesota State Medical Association and the American Medical Association.

He is survived by his wife.

JOHN G. W. HAVENS, M.D.

Dr. John G. W. Havens, 90, former Austin EENT specialist, died May 4, at the home of his niece in Minneapolis. Dr. Havens practiced medicine more than fifty years, most of this time in Austin, where he also was well known as a Dahlia grower, an astronomer and portrait sketcher. One day before his 87th birthday, Dr. Havens closed his office in Austin.

Born in Burrsville, New Jersey, he received his medical degree from the University of Pennsylvania Medical School and in 1907 left Philadelphia to set up an office in Cloquet, Minnesota. He remained in Cloquet until shortly after the devastating forest fire which consumed much of that area. From Cloquet he moved to Owatonna, and in 1920 moved to Austin.

He was a member of the Mower County Medical Society and the American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his niece, Mrs. H. G. Sirk.

JOHN deJ. PEMBERTON, M.D.

Dr. John deJ. Pemberton, 80, a pioneer in goiter surgery at the Mayo Clinic, died May 18. Born in Wadesboro, North Carolina, Dr. Pemberton received his medical degree at the University of Pennsylvania.

He became a resident of the Clinic in 1913, ten years after the institution was founded. He retired in 1952 after thirty-four years as head of a surgery section. Dr. Pemberton was president of the Clinic staff from 1942 to 1945.

Dr. Pemberton was a fellow in the American College of Surgeons and a member of the American Medical

Association, the American Surgical Association, the Southern Surgical Association, the Southern Medical Association, the Societe Internationale de Chirurgie, the Society of Clinical Surgery, the Alumni Association of the Mayo Foundation, the Zumbro Medical Society and a 50 Club and Associate Member of the Minnesota State Medical Association.

He is survived by his wife, four sons and a daughter.

BENJAMIN I. DERAUF, M.D.

Dr. Benjamin I. Derauf, chief surgeon for the Northern Pacific Hospital, St. Paul, for forty-three years, died May 21, at the age of 73. He retired as chief surgeon of the hospital in 1962.

Born in Creston, Iowa, and a graduate of the University of Iowa Medical School, Dr. Derauf became associated with the Northern Pacific Hospital in 1925.

He was a member of the Ramsey County Medical Society, the American College of Surgeons, St. Paul Surgical Society, Minnesota Surgical Society, Minnesota Occupational Medicine Association, American Medical Association and a Life Member of the Minnesota State Medical Association.

He is survived by his wife, one daughter and three sons, one of whom is Dr. Donald E. Derauf of St. Paul.

THOMAS J. DEVEREAUX, M.D.

Dr. Thomas J. Devereaux, 77, Wayzata surgeon, died April 30. Born in Elma, Iowa, and graduated from the Rush Medical School in 1915, Dr. Devereaux immediately went into the medical corps of the United States Army. Upon his release from the Army, Dr. Devereaux came to Wayzata to practice medicine.

He was a member of the medical staff of the Eitel Hospital, the Hennepin County Medical Society and the American Medical Association. He was a 50 Club Member of the Minnesota State Medical Association.

He is survived by his daughter.

EDWARD DYER ANDERSON, M.D.

Dr. Edward Dyer Anderson, 75, a former president of the Hennepin County Medical Society, died May 29, in Rougemont, Switzerland.

Born in Duluth, Dr. Anderson graduated from the East High School in Minneapolis and the University of Minnesota Medical School. He served as assistant and associate professor of pediatrics at the University from 1918 to 1954. He retired from practice that year due to poor health and moved to Gstaad, Switzerland.

He was a member of the American Medical Association, the American Academy of Pediatrics and the Northwest Pediatric Society, and an Associate Member of the Minnesota State Medical Association.

He is survived by his wife and four sons.

The Physician's Workshop

The Operative Cystic Duct Cholangiogram

A Simplified Method of Securing the Catheter During Dye Injection

AT TIMES the operative cystic duct cholangiogram forms an integral and important part in the relief of biliary tract disease. This paper deals with a rapid and simplified method of anchoring the cystic duct catheter in place in cases where securing it easily and quickly by means of a ligature is hampered by difficult exposure.

Case Report

A 54-year-old male was admitted to the Veterans Administration Hospital for routine cholecystectomy, following multiple bouts of right upper quadrant pain. Oral cholecystogram had demonstrated multiple small stones in the gallbladder. Operation confirmed this and also revealed a large cystic duct, and it was elected to perform a cystic duct cholangiogram. Before removing the gallbladder the cystic duct was ligated distally and a small opening was made in one wall proximal to the ligature. A polyethylene catheter was next inserted through this opening into the common bile duct. Three small Cushing silver clips were then placed on the cystic duct overlying the polyethylene catheter, both securing it in place and preventing regurgitation and loss of dye into the peritoneal cavity during performance of the cholangiogram. A suture was then sewn through the skin of the abdominal wall and tied around the catheter to further aid in stabilization (Figure 1).

Review of the operative cholangiogram (Figure 2) failed to reveal any abnormalities. The silver clips were then easily removed, and the cystic duct ligated, the gallbladder having been extirpated while the films were being developed. The patient went on to recover uneventfully.

Figure 1

Figure 2

Fig. 1 — Drawing showing the use of Cushing silver clips during an operative cholangiogram. After the cystic duct is ligated, an incision is made in one wall proximal to the tie and the catheter for dye injection inserted into the common bile duct. Cushing silver clips are then applied to the cystic duct to anchor the catheter in place and prevent regurgitation of dye into the peritoneal cavity during injection. As an added precaution to prevent accidental removal of the catheter, an anchoring stitch is placed about it at the skin margin.

Fig. 2 — Photograph of the normal operative cholangiogram of patient, age 54, during routine cholecystectomy (see text for details). Cushing silver clips (arrow) were used to secure the catheter in place during performance of the dye study.

Continued

Comment

Technical difficulty in performing an operative cholangiogram or the unwillingness to prolong a short operation has allowed the surgeon at times to omit this often vital procedure during cholecystectomy.¹

The method just described was developed after considerable time had been wasted during a previous operative procedure while trying to perform an indicated cholangiogram. This resulted from repeated loss of exposure each time an attempt was made to fasten the cholangiogram catheter in place by means of a suture looped and tied both around it and the cystic duct. This use of Cushing silver clips, besides the speed with which they may be applied, has the advantage of utilizing only one hand of the operating surgeon, thereby leaving his other hand and both those of his assistant free to maintain good visualization of the operative field.

While other rapid methods of performing cholangiograms have been devised to offset difficulties of exposure and operating time loss, such as direct puncture of the common bile duct with injection of dye through a 22-gauge needle² or by the development of needles of more sophisticated design,³ we feel that when the cystic duct route is used, the method described offers a safe and easy method of maintaining the biliary tract catheter in place.

A simplified method utilizing Cushing silver clips to anchor the catheter introduced through the cystic duct in order to perform an operative cholangiogram has been described.

The Bridge

Memoirs of a Lady Ambulance Surgeon

During my time at the hospital, the Williamburg Bridge was being built and we lived in the shadow of this great structure, a marvel of engineering in those days. To the average person that is probably what it means. For me, however, it will always spell a great company of living men out in the open and bravely battling the elements, using their flaming forges as they tossed around the red-hot rivets with a breath-taking precision. I used to watch them going from girder to girder, sure-footed, debonair and oblivious of the terrible distances below them. Their jokes and songs rang out on the frosty air, as they built for the use and comfort of coming generations. And then there would be a hurry call and I would find myself passed along like a chip in the wind by the blue coats, who would take charge, when some of those mighty girders missed connections and came crashing down, carrying some splendid fellows with them. As I tried to reassemble the poor mangled forms I had ready always that blessed hypodermic of morphine to assuage their agony. No, that bridge will remain for me always a living, vibrant memorial to the unsung heroes who built it.

—Emily Barringer, M.D.

Special Article

A Demonstration of Anti-Inflammatory Effect of Indomethacin

NEW THERAPY in the rheumatic diseases is always suspect. A major problem in evaluating anti-rheumatic drugs is the lack of easily reproducible objective criteria by which to measure their effects. Indomethacin is a new drug recently released as an anti-inflammatory agent for the treatment of rheumatic diseases. Experimental studies in animals have demonstrated an anti-inflammatory action, and numerous clinical reports have indicated the usefulness of indomethacin in the therapy of arthritic disorders. Yet few of the human studies present clear objective evidence of an anti-inflammatory action of indomethacin. Smyth¹, in a carefully controlled study using some of the best available objective measurements of rheumatic activity, has presented data supporting the efficacy of this drug.

The authors recently had an opportunity to observe an objective, easily monitored manifestation of rheumatoid arthritis which responded dramatically on four occasions to indomethacin. The patient is a 48-year-old white female with classical rheumatoid arthritis under treatment at the Kenny Institute. In the past she suffered from a severe episcleritis* of the right eye, which had been suppressed by her maintenance dosage of 15 mgm. of prednisone daily. During the course of steroid reduction to 4 mg. prednisone daily, a flareup of the episcleritis occurred along with a generalized exacerbation of her arthritis. Indomethacin was administered starting 9/1/65 in a dose of 100 mg. a day with prompt suppression of the episcleritis and reduction of the articular manifestations.

Following discontinuation of indomethacin on 10/11/65 the episcleritis recurred and her arthritis became worse despite continuing the same 4 mg. daily dose of prednisone. The episcleritis was only partially controlled by the daily local use of corticosteroids. On 12/28/65 the indomethacin was resumed with improvement in the articular symptoms and clearing of the episcleritis. On 1/10/66 the drug was discontinued due to a gastrointestinal upset. The episcleritis flared

*See Test Your Word Score Page 1097.

Fig. 1 — Episcleritis right eye 48 hours after stopping indomethacin. Note blepharospasm.

Fig. 2 — Absent episcleritis 6 days after restarting indomethacin.

Continued

SPECIAL ARTICLE

promptly, and on 1/13/66 the indomethacin was resumed with improvement of the episcleritis within 24 hours. As a test the drug was discontinued a third time on 1/18/66 and resumed on 1/21/66 when it was apparent that the episcleritis became worse with interruption of indomethacin and was promptly suppressed on resumption of the drug. An ophthalmologist was called in during this trial to verify the eye changes while on and off indomethacin. A last trial, accompanied by photographic documentation (Figures 1 and 2), was made when the drug was stopped on 2/27/66 with the episcleritis appearing on 2/28/66 and becoming moderately severe by 3/1/66 when the drug was resumed. Again, improvement was noted within 24 hours and suppression was maximal after four days.

Summary

Objective clinical evidence of an anti-inflammatory effect of indomethacin is presented in a patient with classical rheumatoid arthritis and episcleritis, who on four separate occasions developed a flare in her episcleritis which was promptly suppressed by indomethacin.

Tuberculosis

A Revised Tuberculosis Control Program For Minnesota

To speed the control and eventual eradication of tuberculosis in Minnesota, the following recommendations are offered:

I. *Facilities and Personnel*

1. A physician with training in public health and with adequate experience in the control of tuberculosis should continue to be employed by the Minnesota Department of Health as a Tuberculosis Control Officer to coordinate and carry out the anti-tuberculosis program for the entire state. The value of this has already been demonstrated.

2. The additional personnel and facilities necessary for implementation of the tuberculosis control program should be provided by the Minnesota Department of Health to assist physicians and county nurses in the follow-up and management of tuberculous patients and to assist in obtaining epidemiologic data concerning tuberculosis.

3. The public health nursing staff in the counties or areas should be commensurate with the local tuberculosis problem and adequate to conduct a vigorous anti-tuberculosis program.

4. The eight district offices of the Minnesota Department of Health should assume greater responsibility for local tuberculosis control, and each district should maintain a case register.

5. The Minnesota Department of Health should continue, within its capacities, to provide laboratory services for the sensitivity testing of tubercle bacilli when requested by the physician.

6. Mortality from tuberculosis should be reviewed by the Tuberculosis Control Officer of the Minnesota Department of Health.

7. There is need for continued coordination of the entire anti-tuberculosis program, and the logical center for this effort is the office of the Tuberculosis Control Officer of the State Department of Health. The excellent work being done by state and local health departments, school health programs, sanatoria, hospitals, practitioners, the Livestock Sanitary Board, and the voluntary health agencies could be made even more effective by better coordination of effort without reducing the value or prestige of any group.

II. *Case Finding*

1. We should strive by every means possible to encourage the private physician to utilize tuberculin tests and chest x-rays routinely in the care of the apparently healthy as well as of the ill patient, and to use consultation.

2. Tuberculin surveys:

a. Local physicians in cooperation with the local health departments and the Christmas Seal organization should be encouraged to carry out tuberculin testing programs in the public and parochial schools of their areas.

b. Approval is given to the school tuberculin testing program approved in December, 1965, by the Minnesota Tuberculosis and Health Association, based on the NTA Task Force Report. It is stipulated further that this program be regarded as the "minimum standard."

The minimum program for school tuberculin testing shall include school enrollees, transfers at any level, seventh graders and eleventh graders.

If the tuberculin reaction rate is above 1 per cent in any school district, the need for a more extensive testing program is indicated.

A "positive reactor" shall be considered to be one with a reading of 10 mm. or more of induration for extensive follow-up considerations and for the purpose of computing the 1% reaction rate mentioned above.

Reactors with between 5 and 9 mm. of induration should have reaction recorded as doubtful and should be retested within one year. The recommended doses are 5 tuberculin units or 0.1 cc. of 1:1000 O.T.

c. All positive reactors to tuberculin found in school tuberculin surveys should have chest x-ray examinations, with thorough investigation of contacts.

3. All school teachers and school employees are required by law to show freedom from active tuberculosis as evidenced by an annual chest x-ray examination or by presenting evidence of a negative tuberculin reaction within the preceding year.

4. All colleges, trade schools and similar institutions should be encouraged to require a stu-

Continued

dent to have a tuberculin test, and a chest x-ray if tuberculin positive, on admittance to the school.

5. The following groups having an increased incidence of tuberculosis should have chest x-rays and appropriate investigation of any abnormal findings:

- a. Persons admitted to jails and workhouses
- b. Persons admitted to Salvation Army shelters and similar facilities
- c. All food handlers, annually
- d. Persons admitted to nursing homes, rest homes and homes for the aged
- e. All persons more than 15 years of age who are admitted to hospitals or hospital outpatient clinics

f. Contacts of local cases

6. Mobile Unit Chest X-ray Surveys:

a. Chest x-ray mobile units, now available on a statewide basis, should be continued by Christmas seal organizations.

b. Mobile unit chest x-ray surveys should be conducted annually among those having an increased incidence of tuberculosis, such as migrant workers, skid-row inhabitants and residents of congested population centers.

7. Pathologists, private physicians and clinical laboratories should be encouraged to cooperate in reporting all newly discovered cases of tuberculosis.

III. *Treatment of Active Tuberculosis*

1. Adequate diagnostic and treatment facilities should be available to all patients with tuberculosis.

2. Management of tuberculosis by chemotherapy should be recognized as a public health as well as a purely medical problem and responsibility.

3. Treatment of the patient with active tuberculosis must be under continuous medical supervision and should be instituted within a hospital, preferably one specializing in tuberculosis, and hospitalization should continue until the disease is no longer communicable. At present, this is the best means of instituting adequate therapy, of educating the patient about his illness, and of helping him adjust to it. Hospitalization is particularly important to protect the patient's family and the public from infection.

4. The decline in the number of hospitalized tuberculous patients makes it economically diffi-

cult to maintain most of our sanatoria. Therefore, patients should be centralized in hospitals or sanatoria where it is economically feasible, with due regard for the maintenance of high standards of medical care. Sanatorium or hospital facilities must be maintained as long as the need exists. Private and public general hospitals should be encouraged to accept patients with active tuberculosis, but only if satisfactory isolation can be maintained and if the treatment of tuberculosis can be supervised by a physician experienced in the management of the disease.

5. All patients are discharged from sanatoria or hospitals before treatment is completed, and an occasional selected patient is treated without hospitalization. When the patient is referred to the care of another physician, the tuberculosis specialist should make specific recommendations for continued care and follow-up and should maintain close cooperation with patient and physician thereafter.

IV. *Prevention and Prophylaxis*

1. Vaccination with BCG should be considered only in instances in which a non-reactor to tuberculin is going to experience unusual exposure to tubercle bacilli.

2. The Infectious Disease Committee (or other appropriate committee) of private or public general hospitals, together with hospital administrators, should establish and supervise a standardized technic for room isolation of patients with known or suspected active tuberculosis.

3. The Infectious Disease Committee and administrators of all hospitals should organize a tuberculosis prevention program for hospital personnel.

4. The successful program of tuberculosis surveillance among cattle and livestock, established and maintained by the Minnesota State Livestock Sanitary Board, should be continued by that Board.

5. Prophylactic chemotherapy with isoniazid is recommended for the following:

- a. Children up to two years of age who have been exposed to a patient with open tuberculosis
- b. Tuberculin reactors in the preschool age group
- c. Adults and children with known or probable recent tuberculin conversion
- d. Tuberculin reactors under long term steroid therapy

e. Patients with inactive tuberculosis who have never had adequate chemotherapy and are suffering from conditions known to cause increased susceptibility to reactivation, such as diabetes, gastrectomy, silicosis, acute pneumonia, severe trauma or alcoholism, and certain debilitating and terminal diseases such as lung cancer.

V. *Follow-Up and Rehabilitation*

1. The physician in charge of the patient with active tuberculosis must not only supervise treatment, which is necessarily prolonged, but also impress on the patient's mind the need for follow-up treatment and examinations, for the rest of the patient's life. The Health Department, through the Tuberculosis Control Officer, should follow up this patient's illness indefinitely.

2. Follow-up of contacts of patients with active tuberculosis is essential, and private physicians and public health authorities must both assume this responsibility and cooperate fully.

3. In each case of tuberculosis, the goal is: prevention of spread of the disease to others; cure of the patient with tuberculosis with a minimum of inconvenience, expense and disability; and complete restoration to an active productive life. Without rehabilitation, treatment is only partly successful.

VI. *Education, Research and Coordination*

1. Education of the public, physicians and other professional groups in the basic principles of modern tuberculosis control should be persistent and intensive.

2. The private physician plays an essential role in the treatment of tuberculosis. More information regarding control and therapy must be made available to him.

3. Lay and professional organizations and federal and state government agencies should foster and finance scientific research on matters of current importance to tuberculosis control, with special reference to problems in Minnesota.

VII. *Legislation*

1. The legislative committees of the Minnesota Thoracic Society and the Minnesota Tuberculosis and Health Association should work with the State Board of Health and the appropriate committee of the Minnesota State Medical Association for the purpose of proposing legislation regarding tuberculosis care and control to be presented to the Minnesota state legislature.

2. The "means test" should be abolished in Minnesota for all patients being treated for tuberculosis in tax-supported institutions, and all patients in these institutions should be given free medical and hospital care regardless of their ability to pay.

3. Budgetary requests of the Minnesota Department of Public Welfare and the Minnesota Department of Health for improvement of the tuberculosis program in Minnesota should be approved by the state legislature, or if significant changes are considered, the groups sponsoring this joint statement should be consulted before legislative action is undertaken.

Take five...

LABSTIX® provides 5 important urinary findings*—on a single reagent strip! That's *more* information than you can get from any other single reagent strip. You know the results in just 30 seconds—while the patient is still in your office—and readings are reliable and reproducible. LABSTIX is easy to handle, too. Never goes limp, even when wet, because it's made with clear, firm plastic. And results with LABSTIX are easy to read—color contrast between the test areas and the transparent plastic is clearly defined. An unexpected "positive" from testing with LABSTIX may help in detecting hidden pathology before marked symptoms are manifest.

*Blood; ketones; glucose; protein, and pH.

Present physician devotes part of days off in medical missionary work. Starting guarantee \$18,000 to \$26,000 after 4 years. No investment; full partnership after six months. Age no barrier. Contact: Richard Rowe, M.D., Silver Bay, Minnesota 55614.

Opportunity for career in occupational medicine. Opening for full-time plant physician Southern Minnesota major meat packing company. Excellently staffed and equipped in-plant Medical Department. Regular hours, excellent benefits, salary open. Write T. E. Barber, M.D., Box 800, Austin, Minnesota 55912.

Wanted GP, **INTERNIST, PEDIATRICIAN.** Position with six man medical group associated with company prepayment plan in northeastern Minnesota. Well equipped 38 bed accredited hospital next door to clinic, and two large hospitals in community 25 miles away. Internist and pediatrician to work as consultants in clinic and hospital. Ideal for physician desiring small community practice. Full partnership after six months; rotating call schedule; four weeks vacation, sick and study leave; and retirement plan. Group working toward additional periodic extended study or vacation leaves. Age no barrier. Starting guarantee 18 to \$20,000 with increases to 26 to \$28,000 in four years. Contact: Harold B. Leppink, M.D., Community Clinic, Two Harbors, Minnesota 55616.

What's New!

NEW PRODUCT: A combination of Rauwolfia serpentina (Raudixin®) and bendroflumethiazide (Naturetin®) is stated to be greater in its effect than that produced by either agent alone and permits lower dosage. Available as Rauzide, each tablet contains 50 milligrams Rauwolfia and four milligrams of bendroflumethiazide (Squibb).

Febrile reactions to influenza vaccine are reported to be markedly reduced after the use of a new purified influenza vaccine reported at the American Society for Microbiology on 2 May, 1967. (Parke-Davis Company).

Atabrine (quinacrine) has been given intrapleurally and intraperitoneally in the treatment of neoplastic effusions and favorable results are reported in the Annals of Internal Medicine (66:249, 1967). Fever and pleuritic pain were noted after intrapleural injection, but responses were obtained in patients who previously failed to benefit from other agents. This use of Atabrine is experimental and has not yet been cleared by the FDA. (Winthrop Laboratories).

Physician attention is called to a new dosage form of sodium cephalothin, (Keflin, Lilly). The manufacturer is now making available a 4-Gm. ampoule of this antibiotic for use in those cases where particularly applicable.

Frontier Dentistry

Doctors improvised equipment for dentistry. In the Oregon bunchgrass country, Dr. Urling C. Coe regularly functioned at "tooth-pulling bees." Cowboys with toothaches rode to the host ranch from all over the range. Whiskey flasks passed from hand to hand; everybody drank and sang. Out in the yard Dr. Coe placed two kitchen chairs next to one another. His patient sat in one chair while the roistering gang crowded close. Putting his left foot on the seat of the other chair, Coe had his patient lay his head on his knee. Quickly he encircled the man's head with his left arm in a strangle hold and seized his lower jaw with his left hand. Wielding the forceps in his right hand, he grappled with the decayed tooth and pulled it out by brute force. Dr. Coe would pull out thirty to forty teeth at a session. It was a tough experience, agreed the cowboys, but not nearly so tough as having a blacksmith knock an aching tooth out with a punch and hammer.*

Minnesota Medicine at a Glance

Amniocentesis — Spellacy et al.

Page 1055.

This is a report of the spectrophotometric findings of amniotic fluids to which has been added maternal blood and meconium. These studies were carried out in an effort to clear up some of the false positive determinations found on amniotic fluid analyses for fetal erythroblastosis.

It was found that the addition of maternal blood to the amniotic cavity apparently does not increase the pigments used as prognostic indices in the diagnosis of erythroblastosis by amniotic fluid analysis. It was also found that by mixing meconium solution with amniotic fluid, the significant spectrophotometric peaks in the amniotic fluid were not altered. Therefore no false positive findings were created by the addition of either contaminant to the amniotic fluid.

Although this paper does not educe any startling discoveries, it does widen our knowledge in this field. This is certainly an area in which many such basic research testings must be made. In so doing, we may well find that we will gain more information regarding the status of the intrauterine infant. This knowledge, in turn, might then act as a guide in the handling of various obstetrical problems, just as it has in the handling of the erythroblastotic fetus.

Nodular Disorders — Laymon

Page 1059.

Nodular inflammatory lesions of the legs frequently pose diagnostic difficulties. Recognition of the various entities usually depends upon correlation of both morphologic and histopathologic features. Erythema nodosum, erythema induratum, nodular vasculitis, Weber-Christian disease, pernio, superficial thrombophlebitis, and periarteritis nodosa are included among the classic nodular lesions of the legs. Within the past two decades several new nodular inflammations of the lower extremities have been recognized, such as nodular fat necrosis with pancreatic diseases, subacute migratory panniculitis, necrobiosis granulomatosis, embolic nodules, and certain forms of necrotizing vasculitis such as the nodular dermal allergid. The establishment of a new syndrome must be based on a clearly recognizable clinical pattern, a microscopic picture which is sufficiently distinctive to justify its independence and a course which is characteristic enough to indicate the uselessness of a new term which implies differences in pathogenesis, prognosis, and treatment. Recognition of these entities thus aids the clinician.

Mesenteric Artery — Larson and Nydahl

Page 1067.

Acute superior mesenteric artery occlusion is a rare but nonetheless important surgical emergency, because when it is recognized early it can be completely reversed. If it is not diagnosed before bowel necrosis occurs it is usually fatal. It should be considered in all elderly patients with sudden, poorly defined abdominal pain, especially if heart disease coexists. Several presumptive x-ray signs occur, but unfortunately these develop relatively late. Prompt surgical exploration, with embolectomy and bowel resection if necessary, is essential to a successful outcome. If bowel viability is questionable at the primary operation, non-resection, followed by re-exploration twenty-four hours later, is suggested.

Solitary Myeloma of Bone — Ramos et al.

Page 1073.

One of the rarer tumors is the true solitary myeloma of bone. Most of the so-called solitary myelomatous lesions will eventually show generalized spread if they are observed long enough.

This report concerns a 43-year-old man with a solitary myeloma, or plasmacytoma, who had no recurrence or spread during a 13-year follow-up. This lytic lesion involved the third lumbar vertebra, with destruction of the pedicle and expansion of the transverse process on the right. The tumor was removed surgically, and postoperative radiation therapy was given. The lesion showed the typical histologic picture of a mature myeloma. Roentgenologic survey of the rest of the skeleton showed normal findings. Serum electrophoresis did not disclose any abnormalities in protein.

Because this patient did not have any clinical or roentgenologic signs of other myelomas during the long follow-up period, it is concluded that the lesion represents a true solitary myeloma, or plasmacytoma.

Rubella Syndrome — Staub

Page 1079.

Purpura, thrombocytopenia, intra-uterine growth retardation, hepatosplenomegaly and bone changes are the important newly described features of the congenital rubella syndrome. These have been postulated as due to an increased pathogenicity of the rubella virus. This report of careful observations of purpura, thrombocytopenia, and intra-uterine growth retardation, observed half a decade before the recent epidemics, indicates that these features occurred in the past but were not recognized as secondary to the maternal rubella.

Egyptian Remedy for the Uat Disease

If thou examinist a person with a misery in the epigastrium, he has pain in the arm, the breasts, and the belly and he is told that it is the uat disease (the green-sickness) sayest thou, accordingly, "It is caused by death which has entered the mouth and taken up its abode there." Make him a medicine of the following plants: tehua berries, poppies, peppermint, annek, the red seeds of sechet, cook it in oil and let the patient drink thereof. Lay thy hand upon him, his arm is easily extended and free of pain. Say, "This disease has passed through its proper intestinal route to the anus, I shall not repeat the medicine." Circa 850 B.C.*

some allergens are green

whatever their color,
shape, or size...

Benadryl[®]

(diphenhydramine hydrochloride)

PARKE-DAVIS

for control of
allergic symptoms

Whether the allergen is greenish or garish, unseen or unknown, your patient can get symptomatic relief with BENADRYL—the potent antihistamine with antispasmodic action. **INDICATIONS:** Antihistaminic, antispasmodic, antitussive, and antiemetic therapy. **PRECAUTIONS:** Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers if used with diphenhydramine hydrochloride should be prescribed with caution because of possible additive effect. Diphenhydramine

The pink capsule with the white band is a trademark of Parke, Davis & Company.

has an atropine-like action which should be considered when prescribing diphenhydramine hydrochloride. **ADVERSE REACTIONS:** Side effects are generally mild and may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, blurring of vision, vertigo, headache, muscular aching, thickening of bronchial secretions, restlessness, and insomnia have been reported. Allergic reactions may occur.

BENADRYL is available in Kapseals[®] of 50 mg. and Capsules of 25 mg.

00067

PARKE-DAVIS

Lutrexin[®]

HW&D BRAND OF LUTUTRIN

3000 UNIT TABLETS

**IN THE TREATMENT OF FUNCTIONAL DYSMENORRHEA
AND SELECTED CASES OF PREMATURE LABOR AND 2ND
AND 3RD TRIMESTER THREATENED ABORTION**

In controlling abnormal uterine activity, LUTREXIN, the non-steroid "uterine relaxing factor" has been found to be the drug of choice by many clinicians.

No side effects have been reported, even when massive doses (25 tablets per day) were administered.

Literature on indications and dosage available on request.

Supplied in bottles of twenty-five 3,000 unit tablets.

HYNSON, WESTCOTT & DUNNING, INC.

BALTIMORE, MARYLAND 21201

In peptic ulcer... antacid therapy with a new benefit

CONTAINS A BALANCED
COMBINATION
OF THE MOST WIDELY
USED ANTACIDS—
FOR RAPID
NEUTRALIZATION.
PLUS SIMETHICONE—
TO CONTROL
THE FACTOR WHICH
ANTACIDS ALONE
CANNOT INFLUENCE.

Mylanta[®]

- In Mylanta, aluminum and magnesium hydroxides are balanced to minimize the chance of constipation or laxation and still achieve rapid acid neutralization and pain relief.
- The positive action of simethicone helps relieve the painful gas symptoms which often accompany the peptic ulcer syndrome.
- The nonfatiguing flavor and smooth, nongritty consistency of tablets and liquid encourage continued patient cooperation during long-term therapy.

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) of liquid contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. **Dosage:** one or two tablets, well chewed or allowed to dissolve in the mouth, or one or two teaspoonfuls of liquid to be taken between meals and at bedtime.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Picture of low back pain

**Parafon Forte helps to relieve pain,
restore mobility . . . stop pain-spasm feedback**

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 4-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds.

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.
Tylenol® (acetaminophen) 300 mg.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light-headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied:** Scored, light green tablets, imprinted "McNEIL"—bottles of 100.

President's Letter

THIS is a plug for two very worthy efforts which some of you may not know about, but which, if you did, might stimulate your personal interest and action.

I had known about PROJECT HOPE for some time but had not known as much about it as I should until I had the opportunity to visit with Dr. Harry B. Hall of Minneapolis, an old friend and classmate of mine. Harry has been with the Good Ship HOPE on at least one trip, when it went to the Orient. He is a tremendous salesman for the project.

The other somewhat similar effort is Project VIETNAM, sponsored by the American Medical Association. I knew that Dr. Bror Pearson of Shakopee intended to join this group but didn't know all the details until the Atlantic City meeting, when Bror appeared with three other physicians on a TV program, beamed to the AMA members there at the National Meeting. Instead of a tour aboard a hospital ship, such as the HOPE is, this program is strictly for land-lubbers, and is designed to give care to the Vietnamese civilians for a similar period of time, approximately two months, I believe.

Both of these men, and I'm sure there are others available, are willing to come to one of your County Society meetings to tell you about their adventure. We gripe because of a shortage of physicians in many areas of this country, but we have no problems at all when compared to the fantastic lack of adequate medical care in Vietnam. Most of their physicians are serving with the armed forces, leaving 350 physicians to

look after the medical needs of *15 million* civilians.

There are 16 provincial hospitals for civilians, and it requires 24 to 32 physicians to keep the hospital staffs at full capacity. The types of physicians needed most are general practitioners, internists, general surgeons and orthopedists. Small numbers of physicians in other specialties are required from time to time.

These men who have served with either HOPE or in VIETNAM come home with a missionary zeal for the work that is being done. No man or woman should go into medicine without a sincere desire to be of service to mankind, but this ideal gets a bit fogged up in our land of plenty. Your value to people as their physician can be fully appreciated in an adventure of this kind, rekindling appreciation for those things which we so often take for granted here at home.

Can you spare two months of your lifetime to join either of these projects? I'm sure you would find it most rewarding.

Gastric Duplication with Pancreatic Communication

Presenting

as

Pancreatitis

WILLIAM KATZ, M.D.*
GUILLO ANNESSA, M.D.*
Detroit, Michigan

RAYMOND C. READ, M.D., F.A.C.S.*
Little Rock, Arkansas

RECURRENT INFLAMMATION of the pancreas occurs commonly in a city-hospital population. In most cases there is a history of alcoholism; less commonly, biliary tract disease. Rarely, upper abdominal trauma, previous surgery, hyperparathyroidism or drug toxicity precipitate the disorder. We have recently studied an adult negro female who presented with recurrent hyperamylasemia, outlet obstruction of the stomach, and apparent pseudocyst formation. Careful investigation over a period of six months demonstrated none of the usual causes cited above. Surgical exploration revealed a duplication cyst communicating with both the pylorus and the pancreas. There was interstitial inflammation of the duodenum and the antrum leading to partial obstruction of the gastric outlet. This unusual entity is described below.

Case Report

A 34-year-old negro female was first seen in April 1963, with a four-day history of sharp periumbilical pain radiating to the back and associated with nausea and vomiting. Her symptoms were unrelated to diet. She had been experiencing similar episodes increasingly over a period of two years.

Physical Findings

Physical examination revealed a thin woman, height 4' 11", weight 85 pounds, T 98.6, BP 96/70, R 20. She appeared acutely ill. The only positive physical findings were epigastric tenderness and muscle guarding. Laboratory studies showed a hemoglobin of 10.6 Gm%, wbc. 6,400 per cubic mm., blood amylase 936 Somogyi units (normal less than 200) and serum lipase of 3.8 units (normal less than 0.2).

Progress

She was treated non-operatively with bed rest, nasogastric suction, intravenous feeding and intramuscular antibiotics. Her condition improved so that after three days she was placed on a strict ulcer regimen with subsidence of her symptoms. However, the blood amylase and lipase levels remained elevated until the 20th and 28th hospital day, respectively. She was discharged from the hospital with a diagnosis of acute pancreatitis 32 days after admission.

While on the ulcer diet, the patient had occasional mild epigastric distress and vomiting. She was read-

*Departments of Surgery, Wayne State University Medical School, Detroit, Michigan, and the University of Arkansas Medical School, Little Rock, Arkansas.

mitted on January 2, 1934, with another exacerbation. Upper gastrointestinal series at that time suggested the diagnosis of pseudocyst of the pancreas since it revealed persistent antral deformity with some obstruction to the outlet of the stomach (Figure 1). No masses were palpable in the abdomen. Laboratory studies were unremarkable, the triolein uptake study being normal. Sweat tests to rule out cystic fibrosis were negative. A cholecystogram revealed a functioning gallbladder and a normal-sized common duct which was, however, displaced to the right.

Operative Findings

In view of the patient's continuing distress, exploratory laparotomy was performed on February 2, 1934. A 5-cm.-wide mass was found arising from the inferior border of the pyloric antrum attached to the head of the pancreas (Figure 2). The greater omentum was separated and the pylorus opened through an anterior pylorotomy. A stomal opening was found in the mucosa of the pyloric area on its inferior posterior surface (Figure 3). A probe passed into this opening entered an apparent duplication measuring 3×3 cm. The neck of this cyst had perforated interstitially into the wall of the antrum and also into the duodenal wall for a distance of some two inches above and below the pylorus (Figure 4). The mucosa of the duodenum and antrum was thickened and raised into the lumen. The cyst wall was lined with epithelium demonstrated on frozen section to be gastric, containing both mucus-secreting and chief cells (Figure 5). The external wall of the cyst was continuous with the seromuscularis of the gastric antrum and was attached at its base to a lobular extension of the pancreas from which clear fluid could be expressed from multiple lumina into the duplication.

The neck of the cyst was excised and the pyloroplasty closed so as to incorporate the duplication (Figure 6). It was considered unwise to separate the lobules of the pancreas from their firm attachment to the posterior wall of the cyst for fear of damaging the main pancreatic duct. A vagotomy was also performed. The patient made an uneventful recovery and three years later feels well and has gained 53 pounds (Figure 7).

Discussion

Duplication cysts are defined by Gross and

Ladd as hollow structures lined with epithelium similar to that found in the intestinal tract. The muscular coat, usually two-layered, is intimately adherent to and microscopically a part of the contiguous alimentary tract. This case satisfied these criteria. Gastroduodenal duplications are the rarest type.^{1,2} We consider our example to be more likely gastric since it was so lined and was contiguous, at least in part, with the stomach. However, a definite distinction cannot be made since these features are not exclusive. Thirteen per cent of duodenal duplications have gastric mucosa, and more of these communicate with the adjacent bowel or first appear in later life (33% over 20 years of age).³

Schuster and Castleman⁴ report a "muscular" cyst in a five-year-old boy which, although lined with gastric mucosa, communicated with the pancreatic duct. Their patient also had evidence of pancreatitis. Bradbeer⁵ reports a similar case in a 17-year-old white male without evidence of pancreatic inflammation. However, in both of these cases the cyst could be completely excised after ligation of the pancreatic ducts, since in one

it was only loosely attached to the stomach wall and in the other was lying free in the lesser sac.

Aberrant pancreatic tissue has been seen in the wall of gastric and duodenal diverticula; however, in none of these has direct communication with the normally situated pancreas been present. Aberrant pancreas has not been described in duplication cysts of the stomach. McLetchie⁶ reports an infant with a duplication arising from the first part of the duodenum surrounded by annular pancreas. The lesion extended superiorly and herniated through the diaphragm into the thorax posterior to the esophagus.

Obstruction to the stomach is common with duplication cysts. Bishop and Koop⁷ show a roentgenogram of a duplication comprising the antrum, pylorus, and proximal duodenum which has a strikingly similar appearance to our case. In the latter, extrinsic pressure was compounded by inflammation as a result of interstitial rupture of the cyst, presumably secondary to peptic ulceration. It is also possible that the opening of the duplication into the pylorus became ob-

Fig. 6—Schematic illustration of the closure which included removal of the common wall and Heinecke-Mikulicz pyloroplasty.

structed intermittently, resulting in episodic hyperamylasemia similar to that described in vomiting or after duodenal distention. It was interesting that there was no evidence of previous pancreatic necrosis or pancreatitis at the time of surgery as was anticipated preoperatively. The opening into the stomach was probably not an acquired fistula but was congenital, as was the pancreatic drainage, since there was no fibrosis or other signs of inflammation of the stomach itself.

Treatment in our case consisted of internal drainage which is now the generally accepted method, resection being considered unnecessary.⁷ Histologic sections revealed the mucosa of the cyst to contain chief cells, thus resembling fundic mucosa. In Schuster's case an ulcer was found in the mucosa. There is some risk to incorporation of a gastric-lined cyst so close to the duodenum since, if the mucosa is predominantly antral, one could expect to have chronic release of gastrin from alkaline stimulation. However, our patient has remained asymptomatic for three years, making this complication unlikely. It is interesting that she has gained over 50 pounds in weight, although previously a thin woman, suggesting that she had been partially obstructed for some time.

In summary this case is important not only because it is apparently unique, but since it links the two previously described examples of a gastric-lined muscular cyst arising in the pancreas with the relatively common cases of aberrant pancreatic tissue within the wall of an otherwise normal stomach.

William Lyon Phelps

Gargantua?

For centuries intemperance in eating was not frowned upon but taken for granted. An English country gentleman's dinner in 1768 included:

A roasted Shoulder of Mutton and a plum Pudding—Veal Cutlets, Frill'd Potatoes, cold Tongue, Ham and cold roast Beef, and eggs in their shells. Punch, Wine, Beer and Cyder for drinking.

And when the same Rev. James Woodforde gave an "elegant" dinner in 1774, it consisted of the following:

The first course was, part of a large Cod, a Chine of Mutton, some Soup, a Chicken Pye, Puddings and Roots, etc. Second course, Pidgeons and Asparagus. A Fillet of Veal with Mushrooms and high Sauce with it, roasted Sweetbreads, hot Lobster, Apricot Tart and in the Middle a Pyramid of Syllabubs* and Jellies. We had Dessert of Fruit after Dinner, and Madeira, White Port and red to drink as Wine.

A dinner served at the United States Hotel in Saratoga Springs in August, 1890, included:

	Oysters on Half Shell	
	Sauterne	
Green Turtle Soup		Olives
Boiled Salmon		Potato Balls
	Lobster Sauce	
	Sauterne	
Sweetbread Cutlets		Peas
	Claret	
Fillet of Beef		Mushroom Sauce
Lima Beans		Mashed Potatoes
	Champagne	
	Roman Punch	
Supreme of Chicken		Truffle Sauce
Terrapin		Saratoga Chips
Partridges on Toast		Salted Almonds
Lettuce		Crackers
	Cheese	
	Roquefort and Neufchatel	
	Meringues	
	Cigars	
Ices		Fruits
Coffee		Benedictine

*Editor's Note: Today such a dinner would not be considered a treat but a torture or would it?**

—Henry Sigerist, M.D.: Civilization and Disease.

The whole prospect and outlook of mankind grew immeasurably larger, and the multiplication of ideas also proceeded at an incredible rate. This vast expansion was unhappily not accompanied by any noticeable advance in the stature of man either in his mental faculties or his moral character. His brain got no better; but it buzzed more.

—Winston Churchill, 1949

Cardiac and Pulmonary Dyspnea

Clinical Differentiation

DAVID E. DINES, M.D.*
THOMAS W. PARKIN, M.D.
Rochester, Minnesota

ALTHOUGH SHORTNESS of breath is a symptom of various diseases it generally can be classified as one of two types: cardiac or pulmonary dyspnea. The differentiation is important because the treatment is not the same in the two conditions, and the prognosis depends on the correct diagnosis and the proper treatment. The patient with chronic obstructive pulmonary disease and dyspnea can experience respiratory acidosis and coma and can die from being placed in an oxygen tent after receiving morphine sulfate. The patient with coronary insufficiency and pulmonary edema, however, might be improved with an oxygen-tent environment and parenterally administered morphine sulfate. The following two cases in which the presenting symptom was dyspnea illustrate some of the practical aspects in the differentiation of cardiac and pulmonary dyspnea.

Report of Cases

Case 1

A 66-year-old man was seen for the first time on Nov. 18, 1966, because of progressive shortness of breath of seven years' duration; he had been unable to work for the preceding six years. He had smoked one to two packs of cigarettes per day for 50 years and for 20 years had been bothered by a chronic cough which produced one to two ounces of sputum per day. Cold air, fumes, and dust caused him to become choked up and dyspneic.

On physical examination, dyspnea of grade 4 and expiratory slowing of grade 4 were noted. The antero-posterior diameter of the thorax was increased, the chest was tympanitic to percussion, and the diaphragm moved less than 1 cm. bilaterally.

Chronic obstructive pulmonary disease with emphysema and chronic bronchitis was diagnosed.

A chest roentgenogram (Figure 1) showed evidence of emphysema, with hyperaeration in the lower lung fields and fibrosis in the upper. An induced sputum was negative for fungi and acid-fast bacilli. The electrocardiogram showed a pattern of P pulmonale, left axis deviation of QRS, and marked respiratory variation with an S wave in V_1 and V_2 (Figure 2). The actual pH was 7.38 and the pCO_2 was 61 mm. Hg., indicative of a compensated respiratory acidosis (Astrup method). Tests of pulmonary function (Table) show a marked, chronic obstructive pattern.

*Mayo Clinic and Mayo Foundation: Section of Medicine.

A program of therapy for chronic obstructive pulmonary disease was instituted, consisting of the use of a bronchodilator (isoproterenol by nebulization with an air compressor), breathing exercises, and administration of fluids; and the patient was instructed to stop smoking.

Case 2

A 66-year-old white man was seen April 23, 1965, because of dyspnea, nocturnal wheezing, cough, and hemoptysis of seven days' duration. He had been examined on July 21, 1964, for angina and again on March 31, 1965, for angina and bronchitis. He had been a known diabetic for two years and had had an anterior myocardial infarction in July 1964.

Physical examination disclosed an early, short systolic ejection murmur at the left sternal border. The pulmonic valve closure sound was increased in intensity. Diffuse moist rales were heard posteriorly, and the liver edge was palpable 4 cm. below the right costal margin. There was no peripheral edema.

A chest roentgenogram (Figure 3) showed the "butterfly" pattern of acute venous pulmonary hypertension. An electrocardiogram (Figure 4) showed a pattern indicative of an old anterior myocardial infarction.

The patient was treated with diuretics and digitalis. He lost 13 lbs. in nine days and the dyspnea disappeared. A second chest roentgenogram, taken nine days after the first (Figure 5), showed that the heart size was normal.

Fig. 1 (Case 1). Chest roentgenogram showing hyperaeration, depressed diaphragms, and prominent main pulmonary arteries in chronic obstructive pulmonary disease with emphysema. There is fibrosis in both upper lung fields.

Discussion

Dyspnea on the basis of primary lung disease can result from an inability to ventilate, a restriction of the lung volumes, an impairment of diffusion of gas across the alveolar-capillary membrane, and a decreased efficiency of the chest bellows. Each type will increase the work of breathing.

Dyspnea in the cardiac patient results from secondary changes in the lungs. There is a rise in left atrial pressure due to obstruction of the mitral valve (mitral stenosis) or to incomplete emptying of the left ventricle in left ventricular failure. The rise in left atrial pressure is followed by pulmonary vascular engorgement and an increase in pulmonary capillary pressure. The increase in pulmonary capillary pressure causes a transudation of fluid into the interstitial tissue and results in the lungs becoming less compliant. This loss of compliancy increases the work of breathing.

Differential Diagnosis

In the differential diagnosis of cardiac and pulmonary dyspnea, the history and physical examination are most important. *Dyspnea from chronic obstructive pulmonary disease* has an insidious onset, as shown in Case 1 (seven years). The patient usually has a 20- to 50-year history of cigarette smoking, a long history of chronic cough, and a history of wheezing and cough when exposed to dust, fumes, high humidity, and cold air. *Dyspnea of left ventricular failure* is more abrupt in onset, as illustrated in Case 2 (seven days). At first the dyspnea may be evident only with exertion, but without treatment there will be progression to dyspnea at rest, orthopnea, and paroxysmal nocturnal dyspnea. Cough was of long duration and was productive of sputum in our first case, whereas it was paroxysmal, nocturnal, and of short duration in our second case.

Physical examination will often reveal that the dyspnea is of pulmonary origin. There usually will be an increase in the anteroposterior diameter of the thorax, hyperinflation of the lungs, decreased motion of the diaphragms, and expiratory slowing. All of these findings were present in Case 1. If *pulmonary fibrosis* is present, there are characteristic leathery, crackling rales at both

Fig. 2 (Case 1). Electrocardiogram showing P-pulmonale pattern and S waves in V₁ and V₂.

bases, hyperventilation, and restricted breathing. In the cardiac patient there usually are crepitant rales heard posteriorly in the lung bases; coughing will not clear the rales, as it so often does in chronic bronchitis. A diastolic ventricular gallop sound, atrial fibrillation, and cardiac enlargement may be evident. It should be mentioned that patients with chronic obstructive pulmonary disease can present with right ventricular failure, hepatomegaly, and peripheral edema, but the basic points in history and physical examination of the lungs mentioned previously will still be evident.

X-ray Findings

The chest roentgenogram may be helpful in the differential diagnosis. Roentgenographic study may show *no abnormality in chronic obstructive pulmonary disease* or may reveal hyperinflation, widened interspaces, an increased anteroposterior diameter, and flattened diaphragms (Figure 1). The heart size may be normal, but in *cor pulmonale* it is important to look for prominent main pulmonary arteries. This finding was most helpful in our study of 52 patients with *cor pulmonale*, in which 48% showed prominent main pulmonary arteries on the routine roentgenogram of the thorax.¹ If there is pulmonary fibrosis the

Fig. 3. (Case 2). Chest roentgenogram (April 23, 1965) showing butterfly pattern of acute venous pulmonary hypertension with cardiomegaly.

Fig. 4 (Case 2). Electrocardiogram showing pattern of an old anterior infarction.

chest roentgenogram will demonstrate a diffuse symmetric infiltration, but the heart size will remain normal. In *left ventricular failure*, a comparative film may show a recent increase in heart size and an increase in the pulmonary vascular markings or "butterfly-like" densities radiating from the hilar areas, as is shown in our second case (Figure 3). The roentgenogram of the chest in congestive failure also may be of help if Kerley lines (interlobular septal lines),² interlobar collections of fluid, and bilateral pleural effusions (predominantly right pleural) are present.

Pulmonary Function

Tests of pulmonary function can be of help in determining whether the dyspnea is of pulmonary origin. Pulmonary function (Table) in our first case shows a typical pattern of diffuse obstruction to airflow. In left ventricular failure, there can be a decrease in vital capacity and loss of compliance, but the maximal breathing capacity is preserved and there is no air trapping.

The electrocardiogram can be helpful, as it was in our two cases. Case 1 had the typical P-pulmonale pattern³ with tall peaked P waves in II and V₁ and deep S waves in V₁ and V₂ (Figure 2). The presence of a P-pulmonale pattern with right ventricular hypertrophy would lend support to a possible diagnosis of chronic obstructive pulmonary disease. A broad notched P wave in II, III, and a VF and a typical PV₁ pattern⁴ would lend support to left atrial enlargement if mitral valve disease was the cause of the pulmonary congestion. Especially important is the finding of an old or a recent myocardial infarct, as was demonstrated in our second case (Figure 4). This finding lends support to the explanation that the dyspnea was caused by left ventricular failure from coronary insufficiency and previous anterior myocardial infarction.

Treatment

Treatment is important but should not be used as a therapeutic test. The diagnosis should be made prior to beginning treatment. Therapy with digitalis and diuretics is indicated in dyspnea due to cardiac disease, and bronchodilat-

Fig. 5. (Case 2). Chest roentgenogram (May 1, 1965) after digitalization and diuretics.

ing drugs (isoproterenol) are used to improve ventilation in chronic obstructive pulmonary disease. However, we have seen patients who are receiving digitalis and diuretics who have been found to have primary pulmonary disease, and who need bronchodilating medication to improve their ventilation.

Dyspnea on a functional basis⁵ must always be considered in the differential diagnosis. In some instances, functional dyspnea can be suspected, but only by means of a complete history, physical examination, pulmonary function tests, roentgenogram of the chest, and electrocardiogram can such dyspnea be proved to the patient.

Summary

In the clinical differentiation of cardiac and pulmonary dyspnea, an accurate diagnosis as to the cause of the dyspnea is important for proper therapy and improved prognosis. In many cases, an accurate differentiation can be made only after a careful history is taken, a physical examination is conducted, and pulmonary function studies, roentgenograms of the chest, and electrocardiograms are made.

Sometimes a go-getter is sorry he gotter.—Herbert Prochnow

WHAT'S YOUR DIAGNOSIS?

This 61-year-old man was found unconscious at the wheel of his parked car by the police. He had left home less than one hour earlier, feeling well. He had a long history of congestive heart failure, asthma, eczema, emphysema, cortisone use, and osteoporosis with multiple vertebral compression fractures. He had been unable to work for two years, but at the time of this final catastrophe he was up and about and "feeling better than he had in years."

In the emergency room he was cyanotic, pulseless, blood-pressureless, and unconscious. Administration of intravenous fluid, cortisone, and aramine was started. An EKG showed atrial fibrillation and cor pulmonale; a chest x-ray was normal except for the emphysema. Blood sugar was 385 mg% (but the intravenous had already been started). The wbc. was 20,600, the Hgb. 13 Gm. CO₂ 16, K 5.3 Cl 95, Na 135. After about an hour in the emergency room, he regained consciousness enough to name his doctor and to say that he was short of breath but had no pain.

Two hours after admission he was still alert and coherent, but unable to remember anything that had happened or how he got to the hospital. His extremities were cold, cyanotic and pulseless; his pupils were fixed and dilated, and his blood pressure could not be detected.

Four hours after admission he was seen by a medical consultant who felt that he was less responsive than earlier, but noted no other changes in his condition. He agreed that some sort of cardiovascular collapse had occurred and ordered chloromycetin for the white count, bicarbonate for the acidosis, pronestyl for the arrhythmia, levophed for the blood pressure, and an increase in the solu-cortef to 500 mg. every two hours.

Eight hours after admission a distended, tympanitic abdomen was first noted; but the patient was again comatose and still pulseless with no blood pressure. Twelve hours after admission he was dead.

What's Your Diagnosis? Turn to page 1189.

The Corset*

The corset is a product of the baroque period.** Baroque art broke the noble straight line of the Greek pillar and replaced it with the spiral column, developing an architecture of spirals and curves and bulges.

The corset was probably responsible for many of the vapors, faints and fits that befell 18th century ladies. The tighter it was worn, the worse were its effects on health. By compressing the lower part of the chest and the abdominal muscles, it seriously impaired respiration. The corset also deformed the liver, compressing it and displacing it as well as the stomach and other abdominal organs; it exerted pressure on the blood vessels so that respiration, digestion and circulation were badly affected. There is hardly a disease that has not been attributed to the corset. If anything, the corset made the fair sex a weak sex.

—Henry Sigerist, M.D.: *Civilization and Disease*

* See Page 1189.

** Baroque Period—the period from the 16th to the 19th century when art and architecture were characterized by dynamic and extravagant curves and scrolls.

Drugs and Doctors*

Problem in the Production of Certain Behavioral Disorders

ALBERT B. HAGEDORN, M.D.**
RICHARD M. STEINHILBER, M.D.†
Rochester, Minnesota

AS WE REVIEW the history of any drug, we commonly find a great burst of enthusiasm for its use when it is first introduced to medicine. Fortunately this enthusiasm is often justified by the clinical response of the patient. With this enthusiasm, however, some of the complications or untoward side-reactions to the drug are overlooked or missed completely. This is especially significant in view of the recent and current prolific production of new therapeutic agents. Even with well-recognized and long-established drug programs it is not unknown for subtle side-reactions to go unrecognized for long periods. Not all behavioral disorders are neurotic or psychotic in origin. They may be induced by drug therapy, especially in marginally adjusted persons, who seem to have a greater tendency toward adverse reactions to drugs.

The cooperative evaluation of the patient by the internist and the psychiatrist will usually lead to proper recognition of the disorder. We emphasize this mutual concern for the patient. It is almost always necessary for accurate classification and management of the problem.

It is also important to recognize the part that the illicit, inappropriate, or excessive use of drugs may play in the reaction or disorder that we may see in a patient. People learn to use drugs. They learn this most broadly from the culture itself. Generally, a wide variety of drug experience is associated with childhood illness and exposure to physicians, use of medications at home during the formative years, enjoyment of illness because of the pleasant attention it elicits, childhood and adult eating problems for which various drugs are taken with or without medical counsel, and, in adults, cravings for foods and drinks, visits to the physician, and the ultimate and consequent prescribing of more medication.

*Read at the combined meeting of the Minnesota Psychiatric Society and the Minnesota Society of Neurological Sciences with the Mexican Society of Neurology and Psychiatry, Mexico City, March 1 to 3, 1967.

**Section of Medicine, Mayo Clinic and Mayo Foundation.

†Section of Psychiatry, Mayo Clinic and Mayo Foundation.

We are indeed a culture which uses drugs extensively. The enormity of the problem is suggested by the fact that in 1963 drugstores in the United States filled more than 60 million prescriptions for tranquilizers and more than 45 million for barbiturates. These drugs are used in medical care, in home remedies, for keeping awake and going to sleep, and of course socially, as in the use of alcohol. More privately, people may use alcohol, take an antidepressant drug, a tranquilizer, or a barbiturate, smoke marihuana, or sniff glue or gasoline.

Of more significance to our thesis, however, is the part we as physicians play in the genesis of these drug-induced disorders. In conjunction with the prolific production and use of all types of drugs, behavioral reactions are being encountered more frequently. Because the onset of these symptoms may be insidious and subtle or may precisely mimic an organically induced disorder, the role played by drugs is often overlooked. The problem is common to all fields of medicine. Most classes of drugs may be involved at times in contributing to a behavioral reaction. The compounding of medication by the patient himself or even by the physician who, when he prescribes a new drug, fails to admonish the patient to stop taking a previously-prescribed drug, makes the problem more involved. With more and more patients seeking specialized care for each of their problems (for example, seeing a gynecologist, a cardiologist, a urologist, and a general internist concomitantly for separate problems), the patient frequently ends up with similar medicaments from several physicians, each of whom was unaware of what his colleague had prescribed. It is obvious that this excessive medication often becomes a complex problem for the physician as well as for the patient.

We will present four cases as illustrations to point out the urgency for recognition of the part played by drugs in the development of a behavioral disturbance. They illustrate the need for constant vigilance to avoid these adverse reactions.

Reports of Illustrative Cases

Case 1. Impulsive Rage Reaction.

A 23-year-old college senior was brought to the hospital emergency room by her parents because of personality change, unsteadiness of gait, slurring of speech, diz-

ziness, and cloudiness of vision of three weeks' duration. Four days prior to admission she had driven her car off the road, claiming afterward that she had suddenly lost her vision. During the intervening three or four days the patient became increasingly talkative and argumentative and began swearing at her parents. She attempted to contact the local sheriff and a local attorney to enlist their aid in her leaving home, and her parents found it necessary to restrain her forcibly from leaving the house at night.

She was a 5-foot, 1-inch overweight, very heavily mascaraed, peroxide blond who chattered constantly, loudly, and argumentatively during the entire examination. Her speech was heavily slurred and her gait was markedly ataxic. Her pupils were widely dilated and there was gross horizontal and vertical nystagmus.

It was ascertained that she had started taking a methamphetamine-phenobarbital preparation to control her appetite during a weight reduction program five years before, and she had continued taking the tablets in larger amounts (five to six tablets daily) because she found that they stimulated her to such a degree that she could do more schoolwork.

With cessation of all medications her symptoms progressively abated and she became symptom-free. The diagnosis was an impulsive rage reaction secondary to use of a methamphetamine-phenobarbital preparation. She was referred to a local psychiatrist for follow-up psychotherapy.

Case 2. Acute Hallucinosiis.

A 48-year-old housewife complained of generalized fatigue and aching, mostly in the hips and legs, of eight years' duration. She had been taking meprobamate, one tablet (400 mg.) four times a day, for eight years, and in the month prior to coming to us she had increased this to eight or ten times a day. She then abruptly stopped the medication, following which she complained of insomnia and anxiety and suffered anxiety attacks with hyperventilation. Subsequently, she developed hallucinations, delusions, and agitation, requiring admission to the closed psychiatric ward.

The results of physical examination and laboratory tests were normal. A Minnesota Multiphasic Personality Inventory (MMPI) gave results consistent with a psychoneurotic depression.

The history revealed that the patient had a great deal of difficulty with her mother. In addition, she was fearful of becoming pregnant.

When this patient was admitted to the closed ward she was actively hallucinating and was delusional with paranoid ideation, but she was not disoriented. She was given 200 mg. of chlorpromazine (Thorazine) per day; within a three-day period her psychosis subsided and the chlorpromazine was discontinued. After this episode she had no further somatic complaints. She was not interested in any uncovering psychotherapy. She was dismissed without any drugs. The diagnoses were: "psychoneurosis with somatization; acute hallucinosiis secondary to meprobamate withdrawal."

Case 3. Paranoid Confusion.

The third patient was a 59-year-old man who had been in excellent general health but, because of "feel-

ing a little under the weather," went to his local physician, who found no abnormalities. A thoracic roentgenogram showed what appeared to be a huge cardiac silhouette. Although he had no cardiac symptoms, the patient was started on digitoxin. It was later estimated that he was taking 0.6 mg. of digitoxin daily. Eight or nine days later his family brought him to the hospital, stating that he had voided on the living-room rug, that his speech was "bizarre and disconnected," and that he acted very suspicious toward everyone.

On admission to the hospital it was noted that his heart rate was 36 beats per minute, and an electrocardiogram disclosed complete AV block. The thoracic roentgenogram showed a cardiac silhouette which was normal but almost entirely obscured by a large anterior mediastinal shadow that proved to be a large lipoma.

The digitoxin therapy was discontinued and after a week his heart rate and his cerebration returned to normal.

The diagnosis was "paranoid confusion secondary to digitalis toxicity."

He was advised that digitalis was not indicated in his case, and, when seen six months later, he continued to feel and act well.

Case 4. *Delusions of Grandiosity.**

In this example the patient was a 51-year-old white man who had been troubled with rheumatoid arthritis for 10 years. He said he was unable to take aspirin because it upset his delicate stomach. He had tried enteric-coated aspirin but complained that it also upset his stomach. He had been known to believe that two to three times the prescribed dose of a medicine would give two to three times the beneficial effect, ignoring the possible toxic or harmful results of such dosage. Until the previous few years he had been whimsical and jovial and had enjoyed writing clever humorous rhymes. He had always worked very hard and had very few interests outside of work. He always wanted things done immediately, was impatient, would not delay, and was bossy and demanding of his help or partners. He began giving himself cortisone injections 15 months before he was seen by us. Ten days before his consultation he told his son-in-law, who manages his farm, that he had

given himself 40 times his usual dosage of cortisone that day. He had apparently followed a very irregular schedule of cortisone dosage for the previous year. He had suffered a financial setback three months before hospitalization "when he guessed wrong in the grain market." He had been noted to have a flushed, red, and swollen face for three months. For two months he had complained of dizziness on standing. For the most recent month he had begun to get ideas of grandiosity. "The farm began looking like Grand Central Station" in the words of his son-in-law, because he had hired so many people to build new buildings and fix fences, and he had bought many hogs to feed. He always had been pleasant to his wife until eight days before hospitalization, at which time he became verbally abusive to her. He also began writing checks for large amounts of money to strangers.

Hospitalization and reduction of his corticosteroid dosage over a period of two weeks resulted in symptomatic remission. The diagnosis was "delusions of grandiosity secondary to hypercortisonism."

Summary

Overprescription and overmedication often lead to drug toxicity. Four clinical examples are given to stress the diverse behavioral reactions that can result from inappropriate use of common drugs. Indolence in drug prescribing may present problems for the patient; catering to a patient's demands for immediate relief invites disaster. The physician has great need to review the criteria of indications for drug therapy and to continue to base such therapy on the solid tenets of a physical examination and an astute evaluation of the patient's psychosocial environment. Then he can expect that the proper drug will be used in the proper dosage with a satisfactory result.

* See Test Your Word Score Page 1227.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 1186)

At autopsy there was found a dissecting abdominal aneurysm with hemorrhage into both adrenals and kidneys. This case is proof that cortisone cannot cure everything, and that absence of pain does not indicate absence of organic pathology. The case was instructive because of the complete lack of abdominal physical findings until the case was terminal.

First Use of Ether Anesthesia

In the National Statuary Hall in Washington, D. C., Dr. Crawford W. Long's statue bears the inscription: "Discoverer of the use of sulphuric ether as an anesthetic in surgery, on March 30, 1842, at Jefferson, Jackson County, Georgia."

Long had come to Jefferson to set up his practice in 1841, shortly after his graduation from medical school in Philadelphia. Soon hereafter, a "laughing gas" showman intrigued the townspeople of Jefferson with a lecture on the strange effects of nitrous oxide. Anxious to try the gas for themselves, several people asked Dr. Long for a sample. As it happened, the young doctor did not have any on hand but he did have some ether, which, he assured them, would have about the same effect.

Some young men tried the ether in Long's office, became exhilarated, staggered about, laughed and behaved more or less as expected under the circumstances. But Long, more observant than most, noticed that as they staggered and stumbled about, bumping into furniture and bruising themselves, they seemed to feel no pain. Nor did he, himself, have any recollection of pain after joining the ether party and later finding bruises on his body. This set him to wondering about the possibilities of ether. If a small amount of it could mask the pain of a bruise, would a larger amount be able to prevent the more extreme pain of surgery?

Dr. Long answered this question on March 30, 1842. James M. Venable, a participant in the ether experiments, had some tumors on his neck which he had delayed having removed because of his fear of pain. Long suggested that the use of ether might permit a painless operation. Venable agreed to its use. That night Dr. Long poured some ether on a towel and held it over the patient's nostrils until he fell asleep. When Venable awoke, he was astounded to learn that one of his tumors was gone. He had felt absolutely no pain during its removal. The first operation under ether anesthesia was a success and the fee, incidentally, was two dollars.*

* Bernard Seeman: *Man Against Pain*

A Powder Is A Powder!

Ignorance continued sometimes to amuse, more often to anger, doctors. Dr. Ferdinand Herff, who practiced among Texas homesteaders, prescribed seven powders for a farmer's wife who was experiencing severe constipation. The price of the powders seemed high to the farmer, so he went home, and under the supposition that a powder is a powder, gave his wife seven doses of gunpowder instead. When the doctor stopped by to see how the woman was getting along, he found her no better and decided he must give her an enema. He told the farmer, "Bring me two chairs, a syringe, hot water and a lamp.

"Doctor, I bring you the chairs, the syringe and the hot water," said the farmer, turning pale, "but I don't bring you the lamp. That woman has seven charges of gunpowder in her."*

Sweat Chloride Assay for Cystic Fibrosis

Using
Pilocarpine Iontophoresis
Stimulation,
Filter Paper
Collection and
Cotlove Chloridometer
Analysis

LELAND HANSEN*
MARY BUECHELE*
JOANN KOROSHEC*
WARREN J. WARWICK, M.D.*
Minneapolis, Minnesota

WHEN PROPERLY DONE, the assay of the chloride content in sweat is the most reliable diagnostic test for cystic fibrosis. It is also one of the most specific diagnostic tests in medicine when properly done, for true-false positive and false negative tests are almost unknown. Nevertheless, false positive and false negative tests are frequently seen when the test is not done correctly.

In this paper we describe the technique and safeguards we have developed over the past five years plus a simple method for evaluating the results. We use the pilocarpine iontophoresis method devised by Gibson and Cooke¹ with modifications. This test has three distinct steps: (1) stimulation of sweating, (2) collection of the sweat sample, and (3) analysis of the collected sweat.

Stimulation of Sweating

Equipment

1. Direct current power supply with high internal impedance to limit output, capable of delivering at least 1.5 amps, and preferably not more than 2.0 amps, direct current. ABC Oxygen Rental, 2722 East Lake Street, Minneapolis, Minn.
2. Wire leads—2
3. Two flat electrocardiogram type electrodes with a contact surface of about 5 sq. cm.
4. One perforated rubber strap—15" x 1"

Expendable Materials

1. Pilocarpine nitrate—10 gram lots, Mann Research Laboratories, 136 Liberty Street, New York, N. Y. 10006
2. Distilled water
3. Sodium nitrate — Mallinckrodt analytical grade
4. Gauze squares—4" x 4"
5. Rubber bands

*Department of Pediatrics, University of Minnesota Medical School.

This research was supported by grants-in-aid from the Minnesota Cystic Fibrosis Chapter and the National Cystic Fibrosis Research Foundation.

Reagents

1. Pilocarpine nitrate — 1.0% weight volume solution: 1 Gm. pilocarpine in 100 ml. distilled water, made fresh every two weeks and refrigerated between uses.
2. Sodium nitrate—2.0% weight volume solution: 2 Gm. in 100 ml. of distilled water.

Procedure

The electrodes are covered with a double layer of gauze to provide sufficient liquid-holding capacity to insure an even distribution of current and to prevent local hot spots. The gauze is secured to the electrodes with a rubber band. The loose ends of the gauze are trimmed to prevent direct contact between electrodes. (Fresh gauze is used on each patient.)

The electrodes are identified as negative or positive by their attachment to the iontophoresis transformer; the negative lead to the black outlet, the positive lead to the red outlet. The gauze covering the negative electrode is soaked with the 2% sodium nitrate solution. The gauze covering the positive electrode is soaked with the 1% pilocarpine nitrate solution. The soaked electrodes are then placed on opposite sides of the forearm with the positive electrode on the volar

surface (Figure 1). The rubber strap is fastened securely to assure good electrical transmission but not so tight as to cause pain or obstruct blood flow. The electrodes are held as flat as possible to insure an even distribution of current.

The iontophoresis transformer is turned on and the current gradually increased from 0 to 1.5 milliamperes over five to 10 seconds. The iontophoresis current is monitored constantly because slight burns may occur if the current is allowed to increase above 1.5 m.a. After five minutes, the transformer is turned off and the electrodes removed. Two, preferably three, tests are done on each patient, each test on a separate location on one or the other of the patient's arms.

Collection of Sweat Sample

Equipment

1. One forceps—bottle specimen, straight, blunt tip, nickel-plated steel
2. Desiccator, glass
3. Stoppered glass vials, diameter 2 cm., height 4 cm. with ground glass fittings

Expendable Supplies

1. Parafilm squares 2" x 2"

Fig. 1. — Position of electrodes for iontophoresis.

2. One inch adhesive tape—non-porous, water repellent
3. Filter paper 1 $\frac{1}{4}$ " diameter, chloride free, No. 470 Schleicher and Schuell Co., Keene, N. H.
4. Calcium sulfate, W. A. Hammond Drierite Co., Xenia, Ohio
5. Distilled water
6. Gauze squares

Precollection Preparation

The chloride-free filter paper and glass vials are dried over calcium sulfate before use. Glass vials and filter paper are handled with forceps or gauze and never come in contact with the technician's skin.

Collection Technique

After 24 hours of drying, one piece of the filter paper is placed in each glass vial. The stoppered vials and filter paper can be stored indefinitely in a desiccator in this manner. They are weighed to four-place accuracy on the day they are to be used and are placed in small paper bags on which the weight and identification number of the vial are recorded. After weighing, the vials are replaced in the desiccator until just before they are to be used.

The skin area under the positive electrode is washed with distilled water and dried with gauze. Forceps are used to remove the weighed circular piece of filter paper from the weighing bottle and to place it over the skin area where the positive (pilocarpine) electrode has been. The filter paper is covered with a parafilm square. The edges of the parafilm are taped firmly to the arm. An additional piece of tape is placed over any exposed parafilm to prevent the child from scratching or tearing a hole in it. The time is marked on both the tape and the paper bag. The empty weighing bottle is replaced in its paper bag and returned to the desiccator.

After 30 minutes one edge of the parafilm cover is lifted so that the moist piece of filter paper can be grasped with the forceps and quickly placed in the weighing vial from which it came. It is important that the moist filter paper be placed against the side of the weighing bottle to prevent shredding in the assay method to be described. The vial is stoppered and placed in its paper bag in the desiccator. A second weighing of the bottle is made. The weight of the

sample is the difference between the first and second weights. A minimum of 50 mg. of sweat is necessary for an accurate chloride determination.

Discussion

Mistakes made during the collection of the sweat sample can cause the analysis to give abnormally high or low values. The most obvious mistake is to permit evaporation and concentration of the sweat before the second weighing is made. Evaporation is most likely to occur during collection due to a poor seal on the parafilm which covers the filter paper, to delayed transfer of the sweat-saturated filter paper from the arm to the weighing bottle, or to a poor seal on the weighing bottle. If the filter paper disc comes in contact with the skin of the technician at any time, sodium chloride on his skin will cause contamination. Each of these errors will give falsely high sweat chloride values.

If the clean weighing bottle is touched by the technician's fingers, residual oils and electrolytes will adhere to the glass and be weighed as sweat. This error will cause a low sweat chloride value.

Assay of Chloride

Equipment

1. Chloride titrater—Aminco-Cotlove, American Instrument Co., Inc., 8030 Georgia Avenue, Silver Springs, Md. 20910.
2. Schuco autopipettes, 4 ml. chamber, Schuco Scientific Division of Schueller & Co., 250 West 18th Street, New York, N. Y. 10011.
3. Sample vials—40 mm. (height) x 18 mm. (inside diameter) with ground glass covers.
4. Kirk-type pipette or a calibrated micro constriction pipette with a 1% tolerance.
5. Glass rod
6. Forceps, straight without teeth
7. Glass vials, 5 cc. with plastic caps

Disposable Supplies

1. Distilled water
2. Sodium chloride—analytical reagent, Mallinckrodt
3. Acetic acid—analytical reagent, Baker
4. Nitric acid—reagent grade, Baker and Adamson
5. Gelatin reagent—American Instrument Co.

6. Acetone
7. Chloride free cleaning compound (Bon Ami)

Reagents

1. Chloride standard, 10 mEq/L. 584.5 mg. sodium chloride are dissolved in distilled water to make 1 liter of solution.
2. Diluent—to 900 ml. of distilled H₂O add 6.4 ml. of concentrated nitric acid and 100 ml. of glacial acetic acid.
3. Gelatin reagent—to 6.2 Gm. of dry mixture add approximately 1 liter of hot distilled water, swirl until clear. Dispense in 2-dram vials in amounts sufficient for one day's assay. The dispensed gelatin should be stored in a refrigerator and removed as needed. Unused portions of each day's gelatin should be discarded.

Pre-Analysis Procedures

Four ml. of diluent, automatically pipetted if possible, reduce the variability inherent in the technician's pipetting and 4 drops of 12% dextran with 4% glucose are added to the unknown sweat sample. The filter paper is flattened against the side of the vial with a glass rod.

Blanks are prepared by placing a disc of unused filter paper in a vial and adding 4 ml. of diluent. A clean forceps should be used in doing so to prevent chloride contamination. The filter paper is also flattened against the side of the vial.

Titration standards containing 1 micro equivalent (100 μ l. aliquot of 10 mEq/L standard sodium chloride) are prepared. The 100 μ l. aliquot is measured with a Kirk-type pipette or a calibrated micro constriction pipette with a 1% tolerance. The pipette used in preparing the titration standard is rinsed by sucking diluent up into the pipette twice. Distilled water, followed by acetone, is used to clean the pipette between duplicate pipettings.

Titration Techniques

The silver wire generator electrode which projects from the plastic rod at the right front is pushed down until its lower end is almost flush with the upper edge of the stirrer (Figure 2). This electrode is polished each day with the chloride-free cleaning compound. All titrations are done with the chloridometer set for low speed titration. After each titration, the chloridometer time should be set back to zero. Blank

Fig. 2 — Illustration of vial containing filter paper with relationship to positions of the paddle, electrodes, and silver wire of the Aminco-Cotlove chloride titrator.

titration times must agree within one second. Three or four blanks may be needed before agreement is obtained. More than one second difference between repeated blanks may be due to insufficient chloridometer warm-up, inconsistency of filter paper, dirty electrodes, or contaminated glassware. The standards containing 1 mEq. of chloride, titrated in the same manner, must also not have titration time differences greater than one second. The unknowns are then run in the same manner, and their titration times recorded.

Discussion

If rubber is used in dispensing reagents, the sulfhydryl group released from the rubber will titrate as chloride and cause variable and falsely high values for sweat chlorides. Substitute plastic tubing for rubber tubing.

Oxidation of the silver electrodes also gives false high titration times. Titrate electrodes should be polished each day. Titrations run at medium or fast speeds will give less accurate results, particularly in small samples of low chloride concentration. Since the built-in error of the machine increases in significance as the titration time decreases, decrease the significance of the chloridometer's inherent error by using the low speed titration and increasing the titration time.

The end point of titration with the Cotlove chloridometer corresponds with the abrupt increase in current flow between the silver indicator electrodes produced when all the chloride in solution has been titrated and silver ions are still being released.² A false low reading will result if a short circuit is created by foreign material such as shredded filter paper or pieces of lint or gauze lodging between the indicator electrodes. Falsely high readings will occur if the paddle is stopped due to mechanical failure of the machine or blockage by the filter paper. The high reading is the result of the inability of the silver ions to circulate and combine with the chloride ions. The chloridometer technique gives results which are several times more consistent and precise than can be obtained with volumetric titrations.

Calculations

Calculations are preceded by one assumption: that the weight of the sample collected is a reasonably accurate measure of volume, i.e., 50 mg. is equal to 50 μ l. Since the sweat is almost entirely water, the error accepted by this assumption is very small, less than the errors inherent in our weighing technique.

The data needed to calculate the concentration of chloride micro equivalents per unit

TABLE
Table of 10 Normals and 10 C/F
Variations of sweat chloride values in normal and cystic fibrosis
individuals as determined by pilocarpine iontophoresis sweat tests.

Patient	Meq Cl-/L on normal patients				Meq Cl-/L on C/F patients			
	Test No.				Test No.			
	1	2	3	4	1	2	3	4
1	5	6	6	6	87	87	78	92
2	4	5	5	6	89	98	93	100
3	9	8	5	7	113	115	117	123
4	10	12	15	16	75	77	63	66
5	20	20	21	23	71	101	110	119
6	9	9	10	11	62	89	97	118
7	8	8	8	11	92	74	97	110
8	5	7	7	6	93	100	98	89
9	12	16	16	17	102	108	129	129
10	6	7	8	10	110	114	120	105

Four consecutive sweat chloride determinations on 10 normal individuals and 10 patients with cystic fibrosis were done to illustrate normal variation of chloride values obtained from single individuals. Collections of the four sweat samples from each patient were made on the same day, within 4 hours of each other. All titrations of the samples from a single individual were done on the same day.

volume of the unknown sample have been determined above. They are: (1) the time required to titrate one micro equivalent of chloride, and (2) the time required to titrate the unknown number of micro equivalents of chloride in the collected samples.

The steps in the calculation are:

1. *Standard titration time* is the time required to titrate the blank plus the 1 micro equivalent of chloride minus the time required to titrate the blank.
2. *Unknown titration time* is the time required to titrate the unknown minus the time required to titrate the blank.

$$\begin{aligned} \mu\text{eq Cl in sample} &= \frac{1 \mu\text{eq Cl (in Stand.)} \times \text{Unknown Titration Time}}{\text{Standard Titration Time}} \\ \mu\text{eq Cl in sample} \times 100 &= \frac{\text{mg. of sample}}{\text{mg. of sample}} = \text{mEq/L of chloride} \end{aligned}$$

The chloride concentration of at least two of the three samples should agree within 10 mEq/L on normals and 20 mEq/L on C.F. patients (Table). Poor duplication suggests a need to do three more tests and to review collection techniques and analytical procedures.

Results

Since sweat chloride values are skewed to the right and do not form a normal curve, the simplest convenient arrangement for graphic presentation is the cumulative frequency curve, or ogive. The ogives in Figure 3 show the cumulative frequency distributions of sweat chloride values for three groups: 835 normal children under age 13, 105 patients with cystic fibrosis under age 13, and 216 normal individuals 13 and over. These sweat chloride determinations graphed in these ogives were done between January 1963 and July 1966. Similar ogives could be obtained for sweat sodium; however, they would be less satisfactory because the overlap of values from normals and patients with cystic fibrosis is much greater for sodium than for chloride.

It is essential that each hospital doing sweat tests establish its own range of sweat chloride

CUMULATIVE DISTRIBUTION OF Meq / L CHLORIDE
IN SWEAT ON 1,156 SWEAT SAMPLES
READ AS % LESS THAN

Fig. 3 — The above cumulative frequency distribution curves of sweat chloride concentrations are for three age groups: 835 normal children 12 years of age and under, 216 individuals 13 years of age and under, and 105 patients with cystic fibrosis 12 years of age and under.

The mean of those thirteen years and older is slightly higher than that of the 12 years of age and under group. There is a slight overlap of the upper 5 per cent of the normal group and the lower 5 per cent of the patients with cystic fibrosis.

values for normals and cystic fibrosis patients because slight differences in means and distribution of values exist from region to region. We believe these to be few due to variation in collection and analysis techniques; but other as yet unknown factors may be playing a role. A good ogive of normal or cystic fibrosis sweat chloride values can be established with 100 tests. During the period of data gathering, before establishing its own ogives, these ogives can be used.

Values in the lower 95% of the normal range may be considered diagnostic of normal; values in the upper 95% of the range for cystic fibrosis may be considered diagnostic of cystic fibrosis. Values in the upper 5% of the normal range and lower 5% of the cystic range should be reviewed with caution as a slight overlap occurs in this area. Patients whose sweat tests fall in this area should have repeated sweat tests and other diagnostic procedures such as duodenal intubation, analysis of sodium and potassium in nails, and lip biopsy.

Cartilaginous Tumors of the Larynx

Chondrosarcoma of the Larynx

ROBERT M. GASIOR, M.D.*
WILLIAM H. REMINE, M.D.**
Rochester, Minnesota

A MASS IN the neck, especially in the thyroid region, has often been considered a goiter, without much concern as to any other possibility. Because such a lesion may be of cartilaginous origin, the differential diagnosis in any case of a mass in the neck is important. The following is a report of a patient with this rare type of neck lesion who was recently seen at our clinic.

Report of a Case

A 73-year-old white woman was seen at the Mayo Clinic on August 26, 1963, because of a mass in her neck. The mass was located on the anterior right side (Figure 1) and was of approximately 10 years' duration. The patient had been well most of her life and implied to the examiner a very active and vigorous routine of daily living. She is still the sole owner and operator of a small-town dry-goods store, obtaining aid from no one, widowed for 16 years, and childless. One and one-half weeks prior to admission the patient admitted to having walked 1½ miles. Walking this distance was no strain for her at that time or previously. Her history was not significant; she could not recall having had any episodes of severe illness, and no surgery had been done. The patient is postmenopausal, with no reference to unusual difficulty during her "change of life."

Approximately 10 years before, she had noted a small mass about the right side of her neck, which she considered to be a goiter. About six years later the mass began to enlarge and continued to do so to the time of examination on August 26, 1963. The only difficulty the patient had noted with the mass was a coughing tendency with some choking, particularly when she was in the right lateral decubitus position. Dysphagia occurred late in the course of the present condition. The patient denied nervousness, easy fatigability, weakness, intolerance to heat or cold, sweating, dry skin, poor appetite, gain or loss of weight, aching, and palpitation. No medication (including iodine) had been taken.

Physical Findings

Physical examination revealed a well-developed, healthy-appearing, elderly lady with a large mass located about the anterior right side of her neck. The mass was huge and stony hard and was considered to be of thyroidal origin, measuring 12 by 10 by 8 cm. on the right, 8 by 8 by 8 cm. about the isthmus, and possessing at

*Mayo Graduate School of Medicine (University of Minnesota), Rochester: Resident in Surgery.

**Mayo Clinic and Mayo Foundation: Section of Surgery.

least two palpable nodules. Estimated weight was 500 Gm. The trachea was felt in the midline and grade 1 venous congestion and dilatation were noted about the right side of the neck. No bruit or stridor was detected, but minimal hoarseness was present. Neither eye signs nor changes in the skin, hair, or nails were noted and tremor was not present. The patient's blood pressure was 150/75. Her pulse rate was 72 beats/minute and regular in rhythm. Her temperature was 97.6 F.

Laryngoscopy was done and the report read, "Right cord fixed, false cord pushed to middle of larynx, right pyriform fossa full, all presumably from extension inwardly from a large goiter behind the thyroid cartilage."

Laboratory and X-ray Studies

Laboratory studies disclosed the following: Hemoglobin level, 11.7 Gm/100 ml.; erythrocyte count, 4,730,000/cu. mm.; leukocyte count, 5,500 cu. mm.; sedimentation rate, 24 mm. in 1 hour; blood group, B

(Rh —); Venereal Disease Research Laboratories test (VDRL), nonreactive; serum sugar, 64 mg/100 ml.; and protein-bound iodine, 5.4 μ g/100 ml.

Gammagram studies showed some uptake of iodine-131 to the left of the lesion, probably a consequence of palpable thyroid tissue in that region.

Roentgenograms of the chest showed evidence of calcification of the aorta and a large, 8-cm. soft-tissue mass just above the level of the clavicles displacing the trachea to the left, suggestive of goiter (Figure 2). Anteroposterior and lateral views of soft-tissue roentgenograms of the right side of the neck showed a 10-cm. round, soft-tissue mass in the anterior right side of the neck, containing large deposits of irregularly shaped calcium (especially laterally) and displacing the trachea to the left and back (Figure 3). The mass was presumed to be a goiter.

Surgery

The possibilities of adenomatous goiter with calcification, Riedel's struma, or carcinoma were considered before operation. At operation the mass was found primarily in the center of the neck and to the right, markedly displacing the right common carotid artery and the deep jugular vein to a point well lateral to the tip of the ear. Silverman needle biopsy revealed necrotic tissue. Much dissection was necessary before it was found that the mass was invading the thyroid cartilage and was actually arising above the thyroid gland. Laryngectomy was considered but not done. As much tumor as possible was removed; only a small 1.5-cm. region was left on the right side of the thyroid cartilage, which was evidently the origin of the mass. The thyroid gland itself was preserved. A No. 5 tracheostomy tube was put in place through the third tracheal ring in the midline.

Postoperative Course

An uncomplicated postoperative course followed. The feeding tube was removed on the tenth postoperative day, but the tracheostomy tube was retained because the patient had difficulty breathing when the tube was removed earlier. The patient was released from the hospital on the twelfth postoperative day. She was seen several days later at the clinic and was instructed to return in three to four months, at which time reevaluation would be necessary in addition to the possible removal of the tracheostomy tube.

Pathologic Diagnosis

The pathologic specimen from the laryngeal region weighed 430 Gm. and was a lobulated, semien capsulated grade 1 chondrosarcoma, 13 by 9 by 7 cm., with regions of central liquefaction (Figures 4 and 5). Attached to the lesion was a 10-Gm. portion of thyroid showing nonspecific thyroiditis.

Comment

Literature Review

Cartilaginous tumors of the larynx are rare.

Fig. 1 — Neck mass. Chondrosarcoma of larynx.

Fig. 2 — Roentgenogram of chest showing evidence of calcification of aorta and a large 8-cm. soft-tissue mass just above the level of clavicles, displacing the trachea to the left and suggestive of goiter.

Fig. 3 — Roentgenograms of the neck for soft tissues showing a 10-cm. round, soft-tissue mass in the anterior right side of the neck, containing a large amount of irregular-shaped calcium especially laterally (presumably a goiter) and displacing the trachea to the left and posteriorly. *A*, Anteroposterior view. *B*, Lateral view.

Fig. 4 — Surgical specimen from laryngeal region weighing 430 Gm. and lobulated, semien capsulated, grade I chondrosarcoma, 13 by 9 by 7 cm. with regions of central liquefaction. Note calcification throughout tumor.

Fig. 5 — Microscopic evidence of chondrosarcomatous changes. (Hematoxylin and eosin; x225.)

The first case was described in 1822 by Heusinger,¹ who classified these lesions grossly as "chondroides." Subsequently, similar lesions were discovered and described, and by 1961 with the publication of Hora and Weller bringing the total of recorded cases in the literature to 100.²⁻⁸

Twenty-two chondromatous laryngeal tumors were seen at the Mayo Clinic and reviewed in 1962 by Goethals⁹ working with Dahlin and Devine¹⁰; seven of these had been noted by New and Erich¹¹ in 1938 and were included in the previously mentioned 100 cases.

A more encompassing review of the literature was made in 1962 by Cocke,¹² who reported 136 cases of cartilaginous tumors of the larynx, referring to the studies of Gay and associates⁵ and of Hora and Weller.⁸ Seven of the 22 cartilaginous tumors reviewed by Goethals were included in New and Erich's¹¹ study; however, 15 were not included and are to be added for a total of 151 cases.

In the study of 136 tumors by Cocke, 130 were benign; six were malignant and were classified as chondrosarcoma. Of the 22 lesions reviewed by Goethals, 18 were low-grade chondrosarcomas and four were benign tumors.

In 1964, Rao¹³ reported a case of a laryngeal chondromatous tumor involving the epiglottis and classified the lesion as a chondroma.

To these (totalling 152), two additional cases of chondrosarcoma have been encountered at the Mayo Clinic since 1961, bringing the current total to 154. One of these includes the present case report.

Anatomical Features

Most of the reported chondromatous tumors

have developed on the endolaryngeal surface of the posterior plate of the cricoid cartilage, extending inward into the larynx. Lesions have involved other sites: namely, the pharyngeal (posterior) surface of the cricoid or lesions projecting from both surfaces, thyroid cartilage, and epiglottic and arytenoid cartilages. Growth has been found to be characteristically slow and expansile, causing pressure atrophy of contiguous structures and eventual involvement and obliteration of the normal laryngeal framework. Extrinsic growths have resulted in problems of deglutition, whereas intralaryngeal tumors have caused mechanical obstruction of the airway, with impeded movement of one or both vocal cords.

Ewing¹⁴ stated that chondromas usually form as solid, hard, lobulated, rounded tumors, which may attain large dimensions and may become softened by mucinous degeneration and cysts: the cysts are filled with serous, mucinous, or fatty material. Moore³ observed that these tumors usually are sessile and immovable and may be broad and flat, nodular, or irregular and are generally covered by a healthy or slightly hyperemic mucous membrane.

Lichtenstein¹⁵ and Lichtenstein and Jaffe¹⁶ established certain histologic criteria for the diagnosis of chondrosarcoma in cartilaginous tumors. These include richly cellular neoplastic tissue with (1) numerous cells with plump nuclei, (2) cells with multiple nuclei or hyperchromatism of the nuclei, (3) uninuclear giant cells, and (4) irregular-sized cells with irregular-sized nuclei. These criteria were also used by Dahlin and Henderson¹⁷ in their study of 212 chondrosarcomas.

Figi¹⁸ found that the average age for his six patients with laryngeal cartilaginous tumors was 52 years. In studying chondrosarcomas in other sites, Dahlin¹⁹ noted that they were more prevalent in the patients in the fifth and sixth decades, whereas Kragh and associates²⁰ noted an average age of 58.4 years. Males were more often afflicted. With cartilaginous tumors of the larynx, the ratio was approximately 4 to 1.

Slow Growth

Symptoms vary according to site, size, and rate of growth of the tumor, and usually are due to interference with deglutition or laryngeal functions, either respiratory or vocal, or both. Because the tumor grows slowly, onset is usually

insidious. Hoarseness, dyspnea, and the presence of an external neck growth are the usual order in which complaints are presented. In their comprehensive analysis of benign tumors of the larynx, New and Erich¹¹ noted that pain was infrequent and ulceration was extremely uncommon. Moore,³ New,²¹ and Figi¹⁸ found that hoarseness was usually the earliest symptom, with dyspnea the next most common complaint.

Typical laryngoscopic findings, as described by Moore,³ were those of a subglottic, large and round, projecting mass that was situated under one of the vocal cords and extended frequently to the midline of the larynx. Figi¹⁸ stated that the characteristic finding on laryngoscopy was a smooth, sessile^o mass covered with normal mucous membrane in which the blood vessels stand out prominently. Vocal-cord fixation, either partial or complete, may be present and may involve one or both cords. Various authors have described the appearance and examination of the tumor presenting on the external surface of the laryngeal cartilage as being fixed, smooth and hard, and without evidence of inflammation in the absence of glandular enlargement. The diagnosis, ultimately, is dependent on microscopic identification of a biopsy specimen despite the presumptive evidence of such a lesion from the history and laryngoscopic examination.

Roentgenography has proved beneficial, particularly in the presence of calcification, at which time it may be pathognomonic or very helpful when a definitely circumscribed tumor can be delineated.

Other mimicking benign tumors considered in the differential diagnosis, particularly when the lesion is subglottic, are: fibroma, fibrolipoma, angioma, neurofibroma, fibromyxoma, amyloid tumor, adenoma, and cysts of all types.

Treatment and Prognosis

Moore³ stated that the treatment for such growths is analogous to that for carcinoma in the same site and is operative. Prognosis for such patients has been favorable and survival has been relatively long, although local recurrences have commonly appeared after every type of surgical maneuver; recurrences have varied from one to 28 years after operation.

Summary

Chondrosarcoma of the larynx is an uncommon lesion that can simulate a goiter and should be considered in the differential diagnosis of any lesion of the neck. If the diagnosis is verified, the lesion should be treated adequately by surgical intervention. Prognosis with adequate therapy has been good despite local recurrence.

Few people think more than two or three times a year; I have made an international reputation for myself by thinking once or twice a week.

—George Bernard Shaw

Paleolithic Man's Endurance Test

Primitive man was close to nature, but the fallacy of his medicine was its interference with nature. He regarded health and disease as a constant conflict between good spirits and bad spirits, each battling for victory.

The sick person was thus denied rest and quiet, for the disease-demons must be allowed no peace: they must be frightened away by terrifying masks and grimaces; by strange howls, noises, dances; they must be made uncomfortable by beating, biting, pinching, kicking, strangling their host; they must be smoked out by unbearable smells and fumigations. If they were strong enough to endure all this, then by sorcery they must be lured elsewhere, to take their abode in some scapegoat—an animal, or the patient's enemy, or an inanimate object. If they were too clever to be fooled, then they must be appeased with sacrifices and precious gifts. The medicine-man's treatment was so heroic that often he looked as ill and gaunt as his patient, but he never gave up. Even when the struggles of the patient ceased and the soul left his body, the medicine-man would try to blow it back through the various orifices—the mouth, the ear, the anus. Many patients died in their prime, but this merely meant that the demons had conquered—perhaps the deceased had been disrespectful. On the other hand, the medicine-man had many remarkable cures to his credit, and if he kept testimonials, his medicine-bag must have been full of them. In primitive medicine, as in modern, the patient's faith and the physician's personality are important factors in the cure, and often both are the victims of ignorance and suggestion.*

* Victor Robinson: *The Story of Medicine*, 1931.

Medical Men on Postage Stamps

Karl von Rokitansky (1804-1878) Austrian pathologist and pioneer in the science of pathological anatomy, was the first to detect bacteria in the lesions of malignant endocarditis, the first to distinguish between lobar and lobular pneumonia, and the first to describe spondylolisthetic deformities in his study of obstetrics and orthopedics. He also left a classic account of the pathological appearance of the liver in acute yellow atrophy. For his contributions to medical science Austria honored him on a postage stamp issued in 1954.

Jacques Daviel (1693-1762) was a French oculist credited with performing the first cataract operation in 1753. In recognition of his pioneer feat France issued a commemorative postage stamp in 1963.

Accommodating

The patient complained bitterly, "Five dollars is a lot of money for pulling a tooth—just two seconds' work."

"Well," replied the dentist consolingly, "if you wish, I can pull it very slowly."

California Encephalitis

Five
Cases
in
Southeastern
Minnesota

C. M. JOHNSON, M.D.*
C. W. ROGERS, M.D.*
Winona, Minnesota

EACH SUMMER AND fall physicians practicing in the Mississippi River valley area in Minnesota are faced with a difficult problem in the differential diagnosis of illnesses caused by enteroviruses and arthropod-borne viruses. During July, August and September of 1966 Winona, Minnesota, suffered an epidemic of encephalitis. The illness was most often seen in children. Five children who were observed by the authors had a clinical course and laboratory studies specific enough to identify their disease as California virus encephalitis. Prior to 1966 only four cases had been reported in Minnesota. The large number we observed probably represents increased awareness of the presence of this virus and vector^{oo} in Minnesota and improved availability of diagnostic tests rather than increased incidence.

The virus was isolated in 1943 in Kern County, California.^{2,5} It was first thought that the disease did not often extend to man or over a very large area, but later the virus was searched for and found in rabbits, rodents, and squirrels over a wide portion of the West Coast and southern Canada.³ Subsequent studies demonstrated that it can be endemic in character and that several species of mosquitoes are capable of the vector role.^{4,5}

The first recovery of the etiological virus from a human in the United States was made in 1964 from the fatal case of a child who had lived in the Winona section of the Mississippi River Valley. This strain of the virus (there are variations described within the California group) has been labeled the LaCrosse strain. Its isolation was unique in that four years elapsed between the first unsuccessful and the recent successful attempt. The brain had been stored at -40C. during the interval.⁶ A 1963 survey in Wisconsin found that persons carried the antibodies in direct proportion to the time they spent out-of-doors. Although the sampling used in that study

*Department of Pediatrics, Winona Clinic.

**See Test Your Word Score Page 1227.

We are indebted to Dr. W. H. Thompson, Department of Public Health and Hygiene, Madison, Wisconsin, for the determinations which elucidated the virus.

was state-wide, groups tested from the western sections of Wisconsin had a higher rate of reactions.⁷

Diagnostic Criteria

A person is presumed to have been infected with the California encephalitis virus if any one of the following criteria is demonstrated: (1) isolation of virus; (2) a fourfold rise in hemagglutination-inhibition, antibody titer or complement fixation, titer between acute and convalescent specimens; (3) a fourfold fall in hemagglutination-inhibition complement fixation titer between acute and convalescent specimens; (4) a rise in neutralization index of 1.7 logs or greater. The category of presumptive cases was based on significant antibody in a single serum specimen; hemagglutination inhibition equal to or greater than 320, complement fixation equal to or greater than 8, or a neutralization index equal to or greater than 2.0 logs.¹

Case Reports

Case 1

This seven-year-old boy was admitted to Winona Community Memorial Hospital on August 8, 1966, with the complaints of severe headache, fever and irritability for two days. His parents reported that his development and school progress were "slow" and that he had had a "prolonged" febrile seizure at age four-and-one-half years. There was a minimal infection of the pharynx; otherwise no foci of infection were noted. His temperature was 103 degrees. Nuchal rigidity appeared on the second hospital day and a spinal tap revealed twenty cells, all of which were lymphocytes. The sugar was 47mgm.% and the total protein 28 mgm. His urine examination was normal.

He was treated for two days with chloramphenicol 20 mgm/kg. and procaine penicillin 1,000,000 units each day. During this interval he developed a transitory weakness of his left arm and hand as well as periods of mental confusion. These symptoms cleared, his need for sedation diminished, and his temperature became normal on the fourth day. He was discharged on August 16; reexaminations on August 30 and November 10 revealed no sequelae. The following is his serologic report:

Complement-fixation titer	September 10	October 3
Mumps	negative	negative
Western equine enceph- alomyelitis	negative	negative
California enceph- alitis	8/10	8/30
HI titer	1:20	1:20
C. F. titer	1:4	1:16

Neutralization (logs)
greater than 3:2

Tests for Eastern, Western, St. Louis, and Powassan encephalitis were negative.

Case 2

This four-year-old boy entered the local hospital on September 9, 1966, complaining of headache and vomiting. On the day prior to admission he was seen in the Winona Clinic because of vomiting and low-grade temperature (100.4). "Vesprin" (trifluoromazine hydrochloride) four mgm. in divided doses was given; however, the vomiting and cephalgia increased. The temperature was 101.4R on admission and nuchal rigidity was present. The urinalysis was normal. The initial hemogram revealed a hemoglobin of 11.8 Gm.; wbc. 13, 550; hematocrit 34%; differential, 73 segs. 5 bands, eosinophil, 19 lymphocytes and 2 monocytes.

The child's vomiting subsided and no intravenous fluid therapy was required. The temperature fell to normal on the fourth hospital day. He ate well after the second hospital day and played without evidence of neurological impairment. Reexamination on October 3 revealed no sequelae. The serologic report is as follows:

Complement-fixation titer	September 10	October 3
Mumps	Negative	Negative
Western equine enceph- alomyelitis	Negative	Negative
California enceph- alitis	9/10	10/3
HI Titer	less than 1:10	1:40
C. F. titer	less than 1:4	1:16
Neutralization (logs) greater than 3:3		

Serologic tests for Eastern, Western, St. Louis, and Powassan encephalitis were negative

Case 3

This nine-year-old boy complained intermittently of a headache for a week prior to his admission on September 26, 1966. On the day prior to hospitalization a marked photophobia accompanied by vomiting developed. His temperature was 101.2R at the time of his initial examination. Nuchal rigidity was present. The urinalysis was normal. The hemogram was as follows: a hemoglobin of 12.9 Gm., wbc. 22,850; hematocrit 37%, differential: segs. 71, bands 6, basophils 1, and lymphocytes 22.

The vomiting was intermittent during the first two days but not severe enough to pose a hydration problem. The headache and photophobia subsided during the first three days. He was discharged on October 1 and reexamined on October 20. No sequelae were noted. The patient's serologic report is as follows:

Complement-fixation titer for	September 28	October 20
Mumps	1:8	1:8
Western equine enceph- alomyelitis	negative	negative
California enceph- alitis	9/28	10/20

CALIFORNIA ENCEPHALITIS—JOHNSON AND ROGERS

HI titer	1:10	1:20	1:20
C. F. titer	1:4	1:16	1:16
Neutralization (logs) greater than 3:2			
Serologic tests for Eastern, Western, St. Louis, and Powassan encephalitis were negative.			
No virus was isolated from a stool specimen collected on September 9.			

Case 4

This five-year-old girl began complaining of a headache and photophobia on September 26, 1966. Two days later she began to vomit and was brought to the Winona Clinic. Her temperature was 100.4 degrees and a slight nuchal rigidity was noted. It was decided to observe the child at home; the mother is the night supervisor at our local hospital. The vomiting quickly subsided and she became afebrile on the fifth day. The headache improved, but the child continued to exhibit stiffness and soreness of the back. There was no tripod positioning; she was able to accomplish the "kiss the knee" test without drawing her knees up or showing hamstring tightness. A stool culture for virus isolation was negative. She was mildly confused for three days and photophobia persisted for ten days. At the end of the second week she resumed her normal play activities. Reexamination on October 19 revealed no residua. The serologic findings are as follows:

Complement-fixation	September 28	October 19	
Mumps	negative	negative	
Western equine encephalomyelitis	negative	negative	
California encephalitis	9/28	10/19	11/11
HI titer less than	1:10	1:10	1:10
C. F. titer less than	1:4	1:16	1:32
Neutralization (logs) greater than 3:2			
Serologic tests for Eastern, Western, St. Louis, and Powassan encephalitis were negative.			

Case 5

This twelve-year-old boy was admitted to the hospital on August 28, 1966, with a four- to five-day history of headache, vomiting, and malaise. He complained of some abdominal discomfort. The child's temperature was 99.6 degrees; no foci of infection were seen and no nuchal rigidity was noted. The urinalysis was normal. The hemogram was as follows: 14 Cm. hemoglobin, wbc. 15,650 with a differential of 82 segs., 1 basophil, 11 lymphocytes and 6 monocytes. The urinalysis was normal. On 8/29 the wbc. was 10,550 with a normal differential. The vomiting persisted and he received intravenous fluids for the first twenty-four hours. A nuchal rigidity was noted on August 30, and a spinal tap produced 17 cells, all lymphocytes. The culture was sterile. A stool culture for viral growth collected on the 31st was negative. The headache persisted for four days, then subsided without evidence of neurological impairment. He was discharged on September 2, and reexamined on September 9 and October 28th. No residua were noted. The serologic results are as follows:

Complement-fixation titer	August 31	November 17
Mumps	negative	negative
Western equine encephalomyelitis	negative	negative
California encephalitis		
HI titer	1:10 less than 1:10	
C. F. Titer	1:4	1:8
Neutralization (logs) greater than 3:7		
Serologic tests for Eastern, Western, St. Louis, and Powassan encephalitis were negative		

Discussion

The reporting of California encephalitis has been increasing rapidly during the last four years. The United States *Encephalitis Surveillance* report of the Communicable Disease Center records one case in 1963, 42 cases in 1964, and 59 cases in 1965. The annual summary for 1965 attributes three cases of arthropod-borne encephalitis to Minnesota. Two of these were Western equine encephalitis with one fatality. The third individual had California encephalitis and recovered.^{1,8}

The symptom complex of vomiting, fever, headache, and lethargy found most commonly in this entity is non-specific. A large group of central nervous system pathogens present a similar picture. However, California encephalitis is rare over the age of twenty.⁹ Photophobia can occur in encephalitis from many causes. In two of our cases, however, it was a striking finding. California virus encephalitis is usually a mild disease. All the patients reported here recovered without residual neurologic damage, motor, emotional or mental.

The definitive diagnosis is isolation of the specific virus or an appropriate rise in the antibody titer. Several species of mosquitoes have been found capable of carrying viruses of the California group. Of these *Culex tarsalis* was identified at the farm home of Case 4.¹⁰ *Culiseta inornata*, another vector, is also found in Minnesota. Birds have not been implicated in the role of host, but the small animal reservoir is large and includes rabbits and ground squirrels, which are abundant.⁹

Winona is built on an island of the Mississippi River. High water in the spring and early summer creates poorly drained ponds which afford

good mosquito-breeding sites. The vector population rises several weeks later and the potential exists for an epidemic.

The mildness of the symptoms, their non-specificity and the ease with which these five cases were discovered once diagnostic tests were obtained suggests that in terms of numbers of cases the California encephalitis virus may be an important central nervous system pathogen.

The Minnesota Department of Health plans to offer the specific serologic tests upon request to physicians who suspect a patient to have California encephalitis.¹³ We expect that a high index of suspicion and liberal use of these tests will find many children with the disease.

Conclusion

The five cases of California-virus encephalitis presented showed the usual mild form of the disease.

The recovery of the virus in 1964 from a pa-

tient who lived in southeastern Minnesota, the frequency of high antibody titers in southwestern Wisconsin, the annual late summer-early fall appearance of sickness in children associated with central nervous system symptoms, and the identification of the virus by indirect means in these five cases suggest that this part of the Mississippi River valley is an endemic region.

Families should be informed about the increased hazard of mosquito bites in this area so that appropriate family and individual control measures can be taken.

Although specific therapy is lacking, awareness of the mild clinical course dictates watchful waiting and enlightened supportive therapy.

ACKNOWLEDGMENT

We are grateful for the interest and advice of L. J. Halterman, D.V.M., currently working with the Minnesota Department of Health. Doctor Nelson, Section of Acute Communicable Diseases, and Doctor Halterman arranged for the specimens to be evaluated by Dr. W. Thompson.

The Typical, Atypical, and "Atypical" Ductus Arteriosus

MICHAEL F. LYNCH, M.D.*
Minneapolis, Minnesota

SIXTY YEARS AGO in an address before the Philadelphia Academy of Surgery Dr. John Munro, a Boston surgeon, made a strong plea for the clinical application of ligation of the patent ductus arteriosus.¹ Although his message was published in the *Annals of Surgery* in 1907, it went unheeded, as his medical colleagues never referred to him a patient with a patent ductus arteriosus for surgical closure.

Thirty years ago on March 6, 1937, another Boston surgeon, Dr. John Streider, attempted unsuccessfully to suture ligate a patent ductus arteriosus in a woman with bacterial endocarditis.⁴

One year later at the Boston Children's Hospital Doctor Gross, unaware of Doctor Streider's attempt, did successfully perform the first ligation of a patent ductus arteriosus and entered a new era in cardiac surgery.² Five years later Doctor Gross reported 14 successful cases of division and suture of the ductus arteriosus and recommended this technique as superior to ligation alone.³

Incidence

Statistically, patent ductus arteriosus is a very important lesion and, of the cardiac lesions in the infant, ought to be the third most common, following ventricular septal defect and tetralogy of Fallot.

Etiology

An etiologic association with German measles in the first trimester has been made as well as an association with high-altitude living in Peru. A dominance in females is well recognized and a familial inheritance has now been reported several times.⁵

Anatomy and Physiology

In intra-uterine life blood reaches the descending aorta from the pulmonary artery through the

*From the Departments of Surgery of the University of Oklahoma Medical Center, Oklahoma City, Oklahoma, and the St. Mary's, Northwestern, and Swedish Hospitals, Minneapolis, Minnesota.

Presented by the author as an inaugural thesis before the Minneapolis Surgical Society, February 2, 1967.

fetal communication of the ductus. Embryologically, the ductus originates from the dorsal part of the sixth branchial arch and, although a branch of the left pulmonary artery, the general contour of its course conforms with that of the main pulmonary trunk.

Experimental observation indicates that anatomic closure of the ductus begins during the last weeks of intra-uterine life and continues for several weeks after birth. Normally it closes functionally with the increase in the oxygen of the fetal blood and the lowering of the pulmonary arterial resistance with the first respirations. Subsequently the ductus undergoes fibrosis and remains as a ligament leading to an interruption of the flow of blood. If it remains patent, there is a reversal of the flow and a persistence of the patent ductus arteriosus.

With the increasing use of cardiac catheterization in the late 1940s and early 1950s many patients with open ductus arteriosus were diagnosed, though they were not recognized clinically because of the absence of the typical murmur and the other usual signs of a patent ductus arteriosus. These seemed to occur in very sick children with markedly elevated pulmonary artery pressures from birth which altered the hemodynamics of the shunt, changing the degree of turbulence of flow and thereby the characteristics of a typical murmur, this group constituting the "atypical ductus arteriosus." In addition to these two, there is a group of cardiovascular defects producing systolic-diastolic murmurs which mimic the murmur of patent ductus arteriosus.

The Typical Patent Ductus Arteriosus

Diagnostic Features

Most of the children with the classical, simple, or typical patent ductus arteriosus are asymptomatic, and attention to the defect is made by discovery of the classical murmur in the left 2nd intercostal space. However, a few suffer from recurrent severe respiratory infections, underdevelopment, and easy fatigability. Cyanosis or clubbing^o is never present.

A thrill, systolic or systolic-diastolic, is often noted. Left chest prominence is common and the cardiac impulse is hyperdynamic at the apex. A wide pulse pressure with bounding peripheral

pulses may characterize the large extracardiac left-to-right shunt.

The prominent diagnostic feature, however, is the *murmur* described as the "train in the tunnel" or "continuous roaring," or "continuous machinery" murmur best heard in the left upper sternal border and radiating out along the second intercostal space. The murmur is constant, varying little with breathing or position. It is to be differentiated from other systolic-diastolic murmurs heard precordially, of which the most common deceiver is the so-called venous hum.

A typical machinery murmur or frequently any murmur is very rarely heard at birth in infants with patent ductus arteriosus. The exception is the premature infant. Even if a murmur is recognized or discovered in the first few weeks of life, it is seldom labeled as a continuous one. Most often only a systolic component is heard, probably because only a systolic gradient exists between the two circuits. This may be related to persistence of the fetal type of pulmonary arterial bed. Six to twelve months later, however, in most patients with typical patent ductus arteriosus the characteristic murmur is noticeable.

Procedure Studies

The findings on chest x-ray depend on the magnitude of the left-to-right shunt through the patent ductus arteriosus. A normal cardiac shadow may be present with a small patent ductus arteriosus. In larger shunts, left atrial and left ventricular enlargements are visible, as is a large ascending aorta and aortic arch, prominent pulmonary artery, and pulmonary vascular engorgement.

The electrocardiogram, like the chest x-ray, may be normal in patients with a small patent ductus arteriosus. With a large shunt the increased left ventricular flow work is reflected in left ventricular hypertrophy. Left axis deviation is present in 10 percent of the patients. Vector cardiography is usually consistent with left ventricular hypertrophy.

Cardiac catheterization is not usually necessary in making a diagnosis of typical patent ductus arteriosus. When it is performed, the catheterization should show an increase in arterial oxygen saturation of at least 6 percent in the blood of the pulmonary artery as compared with that in the right ventricle. These studies demon-

*See Test Your Word Score Page 1227.

strate that the pulmonary artery or right ventricular pressures are normal in more than 75 percent of the patients who have a patent ductus arteriosus. The pulmonary vascular resistance is normal in at least 90 percent. The pulse pressure is wide and left atrial pressure is slightly elevated. The pulmonary-systemic flow ratio is more than 1.5:1.0 and occasionally may be as great as 6:1. The catheter may be manipulated across the ductus in a majority of the patients, especially infants. Once through the ductus the catheter usually takes a sharp downward course along the descending thoracic aorta. This is in marked contrast to other aorto-pulmonary shunts such as a truncus or aortic-pulmonary window where the catheter usually ascends. If the catheter after going through the ductus should course upward, a lateral or left anterior oblique projection is able to differentiate from the latter two conditions.

Forward angiography has not been very helpful in differentiating patent ductus arteriosus from other L-R shunts. Retrograde aortography, however, is quite valuable not only in demonstrating the presence of a ductus but in estimating its degree of patency and the size of its shunt.

Complications

The complications of an unattended patent ductus arteriosus are pulmonary vascular hypertension, congestive heart failure, and bacterial endocarditis. The average patient with this anomaly is nearly asymptomatic throughout childhood. Later when the patient reaches the 20s and 30s, fatigue and breathlessness become in-

creasingly noticeable and congestive failure ensues. A very small patent ductus arteriosus may remain asymptomatic throughout life.

Treatment

The treatment for the typical patent ductus arteriosus is surgical closure. Most cardiologists recommend the operative closure for every child with this condition for two main reasons. One is the unlikelihood that the patient without surgery will be able to live a symptom-free life for the average length of time and the other is that normal circulation is completely restored by surgery with a very low mortality.

Initially, the recommended age for surgery was between three and 15 years of age. In recent years surgery is recommended earlier not only for the symptomatic patient but for the asymptomatic as well. If the team in the community, including cardiologist, anesthesiologist, and pediatric nursing personnel as well as the surgeon, are well acquainted with cardiac surgery in small infants, then a policy of treating patent ductus arteriosus surgically when it is first encountered is not only possible but advisable. Early surgery within the first two years of life and frequently within the first year of life is often mandatory in the patients who are sick. In the asymptomatic infant early surgery relieves the over-work burden on the left ventricular myocardium and may reverse pulmonary vascular changes, and if it can be demonstrated as a safe operative procedure, then it is advantageous to perform it early.

Figure

Postoperatively, the heart diminishes in size, pulse pressure becomes normal, electrocardiographic and radiologic evidence of left ventricular hypertrophy disappear, and pulmonary vasculature becomes normal. In most individuals, if the murmur is not gone by the time the patient leaves the hospital, any residual systolic murmur will have disappeared within the first year after surgery.

The Atypical Ductus

The atypical ductus child is the child with elevated pulmonary arterial pressures from birth. This is in contrast to those occasional typical ductus patients who develop elevated right-sided pressures later in life.

Although children with the typical ductus can be in trouble early in life with left ventricular overflow leading to congestive failure in infancy, these children constitute a minority of the large group of typical patent ductus arteriosus patients. On the other hand, a child with an atypical patent ductus arteriosus *as a rule* is a sick child and physiologically falls into one of two groups (Figure).

The first group is made up of infants with large patent ductus, tremendously increased pulmonary blood flow, and normal or only slightly increased pulmonary vascular resistance. A systolic murmur is heard best at the 2nd to 3rd left interspace and an early diastolic murmur is also heard frequently but, when present, forms a to-and-fro murmur rather than a continuous one. These children, like those with large ventricular septal defects, have a stormy infancy with attacks of pneumonia, pulmonary edema, and congestive failure. This difficult period is followed by a relatively symptom-free childhood. Not until later in adolescence does pulmonary vascular obstruction occur with reversal of shunt, cyanosis, and death.

The second group is made up of patients with only a moderate-sized ductus with pulmonary vascular obstruction. These children are cyanotic from birth. They are small, thin, and scrawny. Their auscultatory findings are the least typical. Their electrocardiogram shows pure right ventricular hypertrophy, and cardiac catheterization demonstrates pulmonary vascular resistance equal to or higher than systemic resistance.

The chest x-ray in atypical ductus always demonstrates or portrays gross abnormality. Right

ventricular enlargement is present in addition to the left, as is usually seen with typical patent ductus arteriosus. The pulmonary artery is prominent as usual. In many advanced cases of the pulmonary vascular obstructive type the peripheral lung fields may be ischemic in contrast to and accompanying the engorged hilar vessels.

Dr. Glen Cayler has shown a good correlation between an electrocardiogram and the pulmonary artery mean pressure in infants with ductus.⁷ Pure right ventricular hypertrophy is always associated with a mean pressure greater than 50 mm. of mercury, and pure left hypertrophy is never associated with a mean pressure higher than 50 mm. of mercury.

Cardiac catheterization, mandatory in atypical patent ductus arteriosus, in addition to demonstrating the levels of the shunt, will point out the degree of pulmonary hypertension as well as the magnitude of the shunt and the nature of the pulmonary arterial bed. As mentioned for the typical patent ductus arteriosus previously, aortography or dye injected from the systemic side will demonstrate sharply the left to right shunt, while right to left shunts are well shown by pulmonary artery injection.

Treatment of Atypical Ductus

The outlook for patients with atypical ductus unattended can be summed up as that of progressive pulmonary vascular obstruction. However, the treatment of the atypical ductus patient cannot be summarized as easily as that for the ductus patient without pulmonary hypertension. The atypical ductus with high flow and normal pulmonary vascular resistance offers no problem in recommending surgical correction. Nadas⁶ feels that as the increased flow and pressure throughout the pulmonary bed are present during the entire cardiac cycle, progressive pulmonary vascular obstruction may occur sooner in infants with large patent ductus arteriosus than in those with large ventricular septal defects. In view of this possibility of progressive pulmonary vascular obstruction, operation, if it can be performed safely, is indicated as soon as the diagnosis is made.

The decision for surgical treatment of the child with high pulmonary vascular resistance is much more difficult to make. Without surgical intervention on the ductus these patients die at an early age. However, surgical closure involves a

high risk and the survivors may still carry the same established pulmonary vascular resistance which occasionally has been shown to increase to an even greater level postoperatively. Various plans of surgical management have been advised. One can summarize these by stating that if the calculated shunt is predominantly left to right, surgical closure is advised. If predominantly a right to left shunt (cyanotic), closure of the patent ductus arteriosus is contraindicated. In the border-line cases of near balanced shunting the surgeon constricts the ductus and watches the behavior of the heart and the pressure in the main pulmonary artery.

Imitators of Ductus Arteriosus

Many people feel that the diagnosis of typical patent ductus arteriosus at least beyond the age of infancy, should be made on clinical grounds alone. However, as mentioned earlier, other cardiovascular anomalies with systolic and diastolic murmurs in the vicinity of the second left interspace may mimic patent ductus arteriosus and may require differentiation. These are listed in the Table. A jugular venous hum is probably the most common deceiver. Specific differentiation of the characteristics of each defect is beyond the scope of the present report and the reader is referred to the appropriate pediatric cardiology text. One such case, however, that of an A-P Window, because of its anatomic and surgical similarity, is included with license in the present list of ductus cases. In view of its rare successful management by direct division and suture, this case has been reported in a separate communication.

Comments

The present report includes 25 consecutive

TABLE

The Imitators of Patent Ductus Arteriosus

Defects which mimic a ductus arteriosus with systolic murmur is in vicinity of the second left interspace.

1. Jugular venous hum
2. Aortopulmonary septal defect
3. Coronary arteriovenous fistula
4. Pulmonary arteriovenous fistula
5. Collateral arterial circulation
(Coarctation of aorta) (Tetralogy of Fallot)
6. Ventricular septal defects with aortic regurgitation.
7. Ruptured sinus of Valsalva
8. Truncus arteriosus

cases surgically treated. Forty-four percent were under the age of two and most were symptomatic, requiring attention at an early age. This prompted earlier diagnosis and surgery and led to the present thesis that surgery at an early age is just as safe as surgery performed later. It should also be noted that only three patients exhibited cyanosis and all three had associated cardiac defects. The typical murmur was heard in only 13 cases.

Only one chest x-ray was interpreted as being normal. Cardiac enlargement and increased pulmonary vascularity were common findings. Specific chamber enlargement in an infant is difficult to ascertain on a routine chest x-ray, but occasionally individual chamber enlargement was defined by the radiologist with the aid of cardiac fluoroscopy.

In order to separate the typical from the atypical ductus arteriosus the pulmonary artery pressure is a single test that will make this differentiation.

The results show that there was no mortality and no significant morbidity delaying the patient's discharge. Closed thoracotomy for recurrent postoperative pneumothorax was performed in one child. Six children showed systemic hypertension, usually of a mild degree for one to six days postoperatively. There were no wound infections. One child underwent right middle lobectomy for chronic bronchitis and bronchiectasis three years after closure of the ductus. Another child, listed as only a fair result, was extremely ill for as long as six weeks postoperatively in the hospital and 10 months later was still not gaining, weighing only 12 pounds, nine ounces. He probably represents the atypical ductus with high pulmonary vascular resistance, although the extent of resistance was never calculated.

Enthusiasm for the results is modified and listed as only very good in several cases by the remaining presence of associated defects or physical or mental limitations. As far as the ductus was concerned, the postoperative course of these patients was excellent.

Summary

The clinical features of typical and atypical patent ductus arteriosus have been reviewed and other cardiovascular defects simulating ductus clinically have been listed.

Earlier surgery for patent ductus arteriosus is strongly advocated not only to salvage the atypical patent ductus arteriosus patient from that large group of infants mortally condemned with cardiovascular defects in the first year of life, but in the typical ductus patient as well, so as to relieve the left ventricular myocardium of its overwork and to restore the pulmonary vascular bed to normal sooner.

Recognition of the defect mimicking ductus before surgery so as to plan a proper approach is demonstrated by a case of aorto-pulmonary fenestration.

A consecutive case series is presented to demonstrate the safety of such surgery in a ductus group with an unusually high percentage of infants of younger age.

Rural Scholarship Pays Off*

Dear Dr. and Mrs. Sheppard,

My husband has gone to deliver our neighbor's first baby: one of his first patients.

As I sit here waiting anxiously for the results I was impelled to write and thank you for making this good life possible for both of us through the benefits of the Rural Scholarship which we accepted a few years ago. We so thoroughly appreciate what you have done to help get us started.

I know that there are other young women with doctor husbands who will soon be setting up practice in rural Minnesota as we have done. I know that some of these wives may have misgivings about leaving the city, and if I knew who they were, I would like to write to them to let them know what a wonderful life it is to be the wife of a general practitioner in this beautiful state of ten thousand lakes. Life is never dull and the people in a small town are delightful. They are truly interested in the worthwhile things in life and are wholly without the numerous tensions of a metropolitan center. I wish I could somehow encourage more young doctors and their wives to locate in one of these invigorating smaller cities of Minnesota where every day is filled with new and stimulating happiness.

Lorna Wing
Sleepy Eye, Minnesota

*This is a scholarship given to medical students by The Minnesota State Medical Association. \$1,000 each year for four years is given to the recipient of the scholarship with the stipulation that after a year's internship, the doctor will practice for five years in a rural area.

YOUR HEALTH—MR. PRESIDENT!

Theodore Roosevelt (1858-1919)

A kaleidoscopically changing pattern characterizes Theodore Roosevelt's health history—marked by novelty, frequency, and violence. No President, preceding or succeeding, met vulnerability to disease and accident with such cavalier invincibility.

In infancy and childhood young Teddy was pathetically puny and spindly, chronically asthmatic and croupy; host to measles, chickenpox, and mumps; and so congenitally myopic that he was never to dispense with thick-lensed spectacles: whence his sobriquet of Four-Eyes. When engaged in active military service in adulthood he always had available a reserve of 12 extra pairs of glasses to allow for breakage on the battlefield.

In 1884 incipient tuberculosis impelled the young man Roosevelt to go ranching in North Dakota, where he engaged in a rugged program of busting broncos, two of which threw him: one for a broken arm and the other for a broken scapula. Fractured bones notwithstanding, he gained enormously in stamina from his year in the Wild West: the year that marked his matriculation from the wan, frail youth into the Rough Rider.

In 1900, while in Colorado campaigning for the vice-presidency, Teddy was accidentally bumped on the chest by a large timber, with no more serious trauma, however, than a severe abrasion. But to him the merest scratch!

After Roosevelt became President his athletic predilections turned to boxing, and during one match his left eye was inadvertently grazed by the glove of his opponent, resulting in retinal hemorrhages followed by retinal detachment. His vision in that eye never returned.

In 1904 a toss from a horse landed the advocate of the strenuous life prone on the ground with such violent impact that his face was unrecognizable behind swelling, cuts, and bruises. Savagely jarred were his neck and shoulders; but no bones were broken, although it was feared for a while that his spine and skull might have been injured.

In 1908 a badly abscessed tooth was extracted.

In 1912, while in Milwaukee to make a speech, Roosevelt was shot in the chest but declined examination of the wound until later. Said he: "I'll make this speech or die." When he approached the lectern on the Auditorium stage and removed his notes from his inner pocket he found a hole bored right through them and blood on his shirt. But that observation failed to deter him from delivering his 90-minute speech in full and with gusto. On later examination of the wound three attending doctors made this statement: "Colonel Roosevelt has a superficial flesh wound below the right breast with no evidence of injury to the lungs. The bullet is lodged somewhere in the chest wall . . . Bleeding was insignificant and the wound was immediately cleaned externally and dressed with sterile gauze . . . As the bullet passed through Colonel Roosevelt's army overcoat, other clothing, doubled manuscript and metal spectacle case, its force was much spent."

On subsequent hospitalization Roosevelt noted meticulously all that was said at his bedside and reported to a friend: "There are only three possible dangers, pleurisy, pneumonia and blood poisoning; the bullet is relatively harmless, but the breaking of that rib might result in pleurisy or even lead to pneumonia, and blood poisoning is a possible late complication from infection of the wound." (In their report the doctors either neglected to mention a broken rib or failed to discover it until later.)

Continued

In 1913, while on a speech-making tour and nature exploration in South America, the Rough Rider was catapulted out of his canoe onto a sharp rock which gouged into his thigh, producing speedy infection, swelling and suppuration with ensuing abscess formations, which subsided temporarily only enough to allow him to continue his safari, about which he said in retrospect: "I had to go. It was my last chance to be a boy." Was he ever not a boy!

In 1918 Roosevelt was hospitalized for a recurring thigh abscess, inflammatory rheumatism, and otitis media in both ears. With medical treatment the right ear cleared up, but the infection in the left ear culminated in mastoiditis—for which no surgery was done and which left him permanently deaf in that ear.

On tour in the Middle West he developed erysipelas in one leg, which failed, however, to daunt his plans or halt his progress. Later, inflammatory rheumatism recurring, he was hospitalized for treatment and then released to retire to his home at Oyster Bay.

On January 5, 1919, the indomitable Teddy died in his sleep of a coronary embolus. He had once said: "Only those are fit to live who do not fear to die; and none are fit to die who have shrunk from the joy of life and the duty of life. Both life and death are part of the same Great Adventure."

Ninth Annual Methodist Hospital Symposium

The ninth annual symposium, sponsored by the Methodist Hospital Staff will be held on Saturday, September 16, 1967 at the Methodist Hospital Auditorium.

The subject of this scientific session is "Rheumatoid Arthritis" and will include the following topics and speakers:

"Rheumatoid Factor and the Pathogenesis of Rheumatoid Arthritis"—Morris Ziff, M.D.—Dallas, Texas

Film: "Examination of Joints"—Part I—Paul J. Bilka, M.D.—Minneapolis, Minnesota

Film: "Examination of Joints"—Part II—Paul J. Bilka, M.D.—Minneapolis, Minnesota

"Basic Treatment Program"—Howard F. Polley, M.D.—Mayo Clinic, Rochester, Minnesota

"Drug Treatment: Steroids, Indocin and Antimalarials"—Charley J. Smyth, M.D.—Tucson, Arizona

"Orthopedic Aspects"—Adrian E. Flatt, M.D.—Iowa City, Iowa

The Minnesota Academy of General Practice has approved this symposium for 6 prescribed hours of credit.

Following the symposium, a dinner dance for all physicians and wives will be held at the Interlachen Country Club, beginning at 6:30 p.m. A charge of \$8.00 per person will be made for the dinner dance, and reservations are required. There is no registration fee for the scientific sessions or the noon luncheon.

All physicians are most cordially invited to attend. For additional information please contact any of the following physicians: David Randall, M.D.—929-4500; Harold Berris, M.D.—588-0661; Edward L. Segal, M.D.—929-1313.

Acute Arterial Occlusion*

IN MOST CIRCUMSTANCES the diagnosis of acute arterial occlusion is not difficult. The finding of a cold, pale, pulseless extremity will alert most physicians that a medical emergency exists. Unfortunately, the clinical situation is not always clear-cut, and disastrous delays in carrying out the proper treatment may result.

Acute iliofemoral thrombophlebitis is not uncommonly confused with acute arterial occlusion. The swollen, pale limb seen in phlegmasia alba dolens** is usually quite tender to palpation, especially in the femoral triangle, and the skin is pale but not cool. The superficial veins are congested rather than collapsed as in arterial occlusion. Because of the associated edema and, more rarely, arterial spasm, pulses may be difficult to palpate; however, after a period of bed rest they usually become palpable. Pain may not be a prominent complaint in either disease. In fact, it is present in only about half of the patients with acute arterial occlusion. Muscular impairment is rarely seen in venous disease but is common in a limb severely ischemic after acute arterial occlusion.

Several points deserve emphasis. First of all, the examination and systematic recording of peripheral arterial pulsations should be a routine part of every physical examination, particularly

in elderly patients. This procedure will aid considerably in a more accurate diagnosis of acute arterial occlusion. Certainly, when a patient complains of pain or distress in an extremity, no matter how bizarre it may seem, prompt evaluation of the peripheral arterial pulsations should be carried out. Prompt diagnosis must continue to be emphasized because unnecessary delays will almost certainly result in the loss of a useful extremity.

During the initial period following acute arterial occlusion, conservative medical management, including the use of heparin, vasodilators, and careful protection of the involved extremity, has continued to be the fundamental means of treatment. Environmental but certainly not local heat is also a helpful maneuver in an endeavor to facilitate vasodilatation. During this time the patient's general medical status can be evaluated for evidence of underlying cardiac disease, such as mitral stenosis or recent myocardial infarction, as a possible source of peripheral emboli. If evidence of significant ischemia persists after several hours of conservative treatment, surgical repair should be attempted, provided the patient's general medical status is reasonable, and even if it is far from being optimal. Advances in surgical technique, including the development of the Fogarty catheter, have made surgical inter-

Ames

vention in acute arterial occlusion much more feasible and effective. Even in the high-risk surgical patient, the arterial occlusion may be corrected and a viable and, even more important, a functional limb may result. In the present-day management of acute arterial occlusion, the sal-

vage of a viable but severely ischemic, painful, and useless extremity can no longer be considered a good result.

Wringer Injuries^{*}

UNFORTUNATELY THE gradual demise of the electric washing machine wringer does not herald the disappearance of the wringer injury. Severe roller-crush injuries are also well-recognized hazards of road and factory accidents. The "ringer foot" is seen when an automobile tire passes over and crushes a foot into soft turf. As in wringer injuries of the hand, initial findings may be minimal and the patient is often sent home without treatment. Because of the foot's dependent position, swelling may progress rapidly and to alarming proportions. Proper immediate treatment is a compression dressing to include the toes and elevation. Partial weightbearing should not be allowed until dependent edema and pain are no longer a problem.

The number of mangle injuries of the hand has increased over the years as more and more homes have become equipped with ironers. These mangles consist of a rolling mechanism and a cast-iron shoe. In this type of injury a profound burn, often third degree, is added to the mechanical trauma of the roller. In very severe cases amputation of digits may occur.

Heavy steel and rubber rollers are not uncommonly found in industrial plants. Mechanized conveyor belts are the very essence of "mass production." Wheels, belts and pulleys are necessary and intrinsic to heavy machinery and, although usually guarded and fenced, a stray finger or hand is never far away. All are capable of

producing crushing injuries which are duplicates or slight modifications of the typical wringer injury.

Reducing edema has always been of immediate importance in the treatment of wringer injuries. This fluid seeps into and around muscles, tendons and ligaments and is gradually replaced by fibrin strands. Eventually connective tissue is laid down and permanent limitation of motion occurs. Sterling Bunnell's maxim, "Edema is glue," is especially appropriate here. In addition to compression and elevation, stellate ganglion blocks to reduce edema have been suggested. Enzymes have also been used to decrease swelling and, while some debate continues, there is increasing evidence that some benefit accrues. Allaben and co-workers¹ measured the volume of the hand and forearm of rhesus monkeys by water displacement. These appendages were then run through a hand-operated wringer and their volumes were subsequently followed post injury. They found edema was considerably less when the animals received enzymes (chymotrypsin in this study), and they noted the first day's dose was the most important. It was suggested that the enzymes should be continued for a total of four days.

There is no controversy on the foundations of treatment: cleansing, compressive dressings, elevation and appropriate surgery when needed. The injury is potentially disastrous and even with a paucity of initial findings treatment should be immediate and thorough.

EDITORIALS

Owen H. Wangensteen, M. D.

May I through the columns of our distinguished Minnesota Medicine relay a message of appreciation and gratitude to my large Clinical Staff in the Twin Cities and to the physicians of Minnesota. In a very real sense, the Physicians of this wonderful community have contributed in a significant manner to the growth in stature and development here of a Great Medical Center.

As I leave the Department of Surgery to spend my remaining days and years in research and upon studies relating to the history of surgery, I would like to indicate to my competent staff and the physicians of Minnesota my warm appreciation of their loyal support of the Medical School, its Medical Center, and the Department of Surgery.

For me it has been a labor of love replete with happy associations and enduring satisfactions. For all this I shall always be eternally grateful to the good people of Minnesota.

Over future decades, the Medical School, I am certain, with continued support from the physicians of Minnesota will continue to grow in stature and in service to the people of this area, as it has over the first 80 years of its existence.

"New" Intra-Articular Steroid

DR. PAUL BILKA's article in the April 1967* issue of MINNESOTA MEDICINE is worthy of comment on several counts. He reports on 298 intra-articular injections in rheumatoid arthritic patients using a new and commercially unavailable preparation called Triamcinolone Hexacetonide. It resembles the two most commonly used intra-articular steroids, namely Prednisolone tertiary Butylacetate and Hydrocortisone tertiary Butylacetate, in containing a TBA radical on C-21 plus an acetonide group on C-16 and C-17.

Dr. Bilka has clearly shown the superiority of the new Triamcinolone drug, with its immediate benefit equalling previously used drugs with a 90% plus benefit, but with its average duration of action being three months instead of one month with hydrocortisone TBA.

He also observed that in 35 joint injections a significant systemic effect from the steroid was noted. If this is true with this new most insoluble preparation, it is even more true with the currently available intra-articular steroids. The

physician should always assume the systemic effect could occur and act accordingly. A patient of mine with a very distant past history of peptic ulcer bleeding bled within 24 hours after receiving an intra-articular steroid. Also the physician should be conservative in his dosage. For example 50 mg. of hydrocortisone TBA is adequate for a knee joint and smaller doses for smaller joints. One should keep in mind that some preparations contain as much as 200 mg. of hydrocortisone equivalent per ml.

An interesting question is raised by Dr. Bilka. He comments on Hollander et al. reporting on Triamcinolone Hexacetonide as far back as 1961. The new Hollander text on arthritis mentions the same drug as the one of choice for intra-synovial therapy. Yet after six years of research use of the drug, it is not available commercially. Let us hope that Dr. Bilka's paper will prod the FDA and Lederle Laboratories into achieving its near future commercial release.

Of Machines and the Man

EPISTEMOLOGY, the formal philosophic inquiry addressing itself to the "How do we know issue?" always seems at the heart of scientific investigation. It operates at and across several levels, ranging from concepts of physiologic imprints on neural tissue (engram theory) to investigations into data accumulation.

This question frequently stifles biomedical investigation. We are dubious of facts offered to us based on an arithmetic mean of observation. The body of statistical lore has become so sophisticated that now we may (and sometimes rather pretentiously) say, "That is good data," or "This is bad data." We can be so introspective about the knowing and learning process that we sterilize productive thinking. And after all, results count for something if not almost everything in science: results in the strict sense of accumulation of data and its organization into a scale of relative approximations to the truth.

Now all this leads us to consider the development of the computer manipulation of physiologic measurements and programmed history forms. Asking a machine to do this is well within the scope of today's technology. One wonders though whether a machine can be programmed to tell us about and then suggest to us a solution to a patient's particular predicament as against a name and a treatment for his disease. What a machine most likely lacks today is what the poets call the tragic vision, the mutation of data into a fine human sensibility.

This aspect of the epistemologic inquiry is quite new. The translation of humanoid sensing into human tenderness and response may be possible soon. Till then the doctor will have to hold his patient's hand, perhaps with his other hand on the keyboard of an IBM.

Robert A. Maslansky, M.D.

After the picnic even Gramps Was a victim of intestinal cramps

Parepectolin for quick relief of acute diarrhea
... soothes colicky pain with paregoric*
... consolidates fluid stools with pectin
... adsorbs irritants with kaolin,
and protects intestinal mucosa

In elderly patients it is particularly important to stop the diarrhea fast. Parepectolin helps you control diarrhea promptly and gain the patient's confidence until etiology has been determined.

Parepectolin®

Each fluid ounce of creamy white suspension contains:

*Paregoric (equivalent) (1.0 dram) 3.7 ml.

Contains opium ($\frac{1}{4}$ grain) 15 mg. per fluid ounce.

warning: may be habit forming

Pectin (2½ grains) 162 mg.

Kaolin (specially purified) (85 grains) 5.5 Gm.
(alcohol 0.69%)

Usual Adult Dose: One or two tablespoonfuls three times daily.

RELIGION IN AMERICAN LIFE

Insects and Other Arthropods as Related to Human Health in Minnesota

IN MINNESOTA, insects and their relatives within the Phylum Arthropoda* are medically important to humans more as direct agents of discomfort or injury than as vectors of disease-producing organisms. This is primarily due to the fact that the State is situated in a northerly region characterized by extremes of temperatures.

Tularemia, or rabbit fever, a bacterial infection which occurs in Minnesota, may be passed by the bite of an infected tick or mechanically inoculated by the contaminated mouthparts of some bloodsucking insect. However, it is more often contracted by handling carcasses of infected rabbits. Meadow mice and other rodents may also harbor the organism. Plague, another bacterial disease maintained by various fleas in a vast rodent reservoir in the western half of the United States, has not been recorded in Minnesota but is found in adjoining western states. It is therefore possible that this organism may now exist undetected in Minnesota, constituting a potential hazard.

A rickettsial infection, Rocky Mountain spotted fever, occurs generally throughout the continental United States, with Minnesota no exception. The etiological agent is passed primarily in the saliva of a feeding infected tick; however, the number of recognized indigenous cases in the central states is relatively low. The last cases recorded in Minnesota were two in 1961.

Probably the most significant arthropod-borne infection of humans in Minnesota is Western encephalitis, produced by a virus carried by certain mosquitoes, presumably from a bird or other wild animal reservoir to humans and horses. This disease was of great importance around 1940 when a large number of cases occurred among humans and horses; but in recent years only a few infections have been noted. A second mosquito-borne arbovirus, that of St. Louis encephalitis, also occurs in Minnesota; but no human illness ascribed to this cause has been reported.

A large group of flies, typified by the house fly, *Musca domestica*, possesses a sponging type of mouthparts, making them incapable of piercing

and drawing blood. These flies may nonetheless become contaminated with any of a number of pathogenic microorganisms. This is especially true for flies that visit fecal materials or feed on exudates from wounds, eyes, or the like. They may either carry organisms externally from such a source or ingest organisms which then may be passed in a viable state via vomitus or feces.

The only insect-transmitted worm that might infect humans in Minnesota, aside from a remote possibility of a tapeworm infection, is the dog heartworm, *Dirofilaria immitis*. This worm is common in dogs and related hosts, especially in the Twin City area, and is presumably carried from host to host by mosquitoes. Although humans are fortunately not suitable for development of adult worms, there have been several instances recorded of apparently asymptomatic encapsulation of larval worms in human tissue. The broad fish tapeworm, *Dibothriocephalus latus*, also present in Minnesota, utilizes a crustacean early in its larval cycle, but the ultimate infection in man is from the fish, not the arthropod.

It is thus evident that the probability of contracting a pathogen from an arthropod is rather remote. Our primary concern, therefore, is with the direct effects insects may have on man. Minnesota is "blessed" with an over-abundance of bloodsucking flies, notably mosquitoes, black flies, horse flies, deer flies, punkies, and stable flies. With reference to mosquitoes, a noted entomologist, over 80 years ago, said, "The bravest man on the fleetest horse dares not cross some of the more rank and dark prairies of Northern Minnesota in June." This statement is as appropriate today as then and could well be expanded to include more than mosquitoes. When these bloodsucking flies feed, they inject a salivary secretion, and the reaction to this bite may vary from virtually none, to itching, to marked swelling around the site of the bite, and in some instances to a more extreme type of response which may require medical attention.

Certain ectoparasitic insects may need a more prolonged and intimate contact with man than the bloodsucking flies. Humans have two species

of lice—the human louse, *Pediculus humanus* (with body and head subspecies), and the crab louse, *Phthirus pubis*—restricted to man alone, living on or near the host and taking several blood meals a day. Bedbugs and fleas are not overly host-specific and will suck human blood if the opportunity presents itself.

The American dog tick or Eastern wood tick, *Dermacentor variabilis*, is extremely common in Minnesota, with the unfed overwintering female and male attaching to humans, as well as to other animals, in the spring and early summer. This tick is virtually the only tick in the State likely to be found attached to humans. Aside from the bite itself and possible secondary infection, this tick is responsible for producing tick paralysis in areas of the eastern United States, but apparently not in Minnesota.* The chicken mite (*Demanyssus gallinae*), the northern fowl mite (*Ornithonyssus sylviarum*), and the tropical rat mite (*Ornithonyssus bacoti*) may occasionally stray from their normal hosts and feed on man, producing a dermatitis. The North American chigger mite (*Trombicula alfreddugesi*) occurs at least in the southern half of Minnesota, and the bite of its parasitic larval stage results in an intense itching and the production of a reddish papule with a minute hemorrhagic center; the bites are found especially on areas where there is clothing pressure, such as under belts or socks.

In the United States there are very few species of spiders venomous to humans, but one of these is *Latrodectus mactans*, the black widow. This spider occurs in Minnesota, although it may be more prevalent in other parts of the United States. Occasional poisonings from the bite of the female may occur in Minnesota.

A number of hymenopterous insects, such as bees, wasps, hornets, yellow jackets, or velvet ants, may sting man by means of a specialized

ovipositor, and, by so doing, inject a venom. The reaction of man to these stings again varies widely, all the way from a transitory pain to rapid collapse and death. Although deaths are rare in proportion to the numbers stung, almost twice as many people die in the United States from bee and wasp stings as from snake bites.

Cases of myiasis—invasion of organs and tissues of man by fly larvae—are occasionally encountered in Minnesota. A skin maggot fly, *Wohlfahrtia vigil*, may deposit a clutch of larvae directly on the human skin, especially of very young children; these larvae will enter and excavate in the skin. Larvae of other assorted species of flies may be classed as occasional invaders of the intestinal tract or secondary invaders of wounds or natural cavities; but, as this is not their normal habit, the observation of viable fly maggots in a freshly passed stool may cause considerable alarm. Larvae of cattle warble flies, *Hypoderma* species, and horse bot flies, *Gasterophilus* species, while normally restricted to living within their livestock hosts, have been recorded from man. Since these flies exist in Minnesota, an occasional human infection may occur.

There are certainly other ways arthropods may affect humans. Some people who have become sensitized to insect particles may develop an allergic response; an asthmatic attack produced by inhalation of air-borne setae** and scales of moths is illustrative of this. Accidental injury may occur to sense organs following collision with or entry by any of a number of insects.

There are a few people who suffer from hallucinations and develop extreme anxieties regarding imagined insect or arthropod attack. These people, suffering from what is termed "entomophobia" or "delusory parasitosis," present a real challenge to those attempting diagnosis and treatment.

External Carotid Ligation for Epistaxis*

ALTHOUGH EXTERNAL carotid ligation is rarely indicated in posterior bleeding, I believe that, if a patient continues to bleed after two attempts of packing, the external carotid artery should be

ligated. The procedure is simple and painless and it shortens the patient's stay in the hospital. Postnasal packing, unless properly applied, causes much discomfort to the patient.

You May Be Right

In the May, 1967 issue of MINNESOTA MEDICINE (p. 673) there appears an editorial which I was invited to write, in a historical, nostalgic manner, referring in particular to the physicians who had practiced medicine in Minnesota for the major part of the past fifty years. I was given the names of twelve men to be inducted into the Fifty Year Club at the annual meeting, and I mentioned them in my article. Because of the proximity of the deadline, I did not have an opportunity to check the galley proofs, so I did not see the finished article until the May issue reached me.

In general, your editors were very kind to me, but there are a few errors which I must correct.

First, after carefully counting on my fingers and verifying with my abacus, I find the names, photographs and biographic sketches of thirteen, not twelve physicians. I mention this because you and others may be checking my arithmetic. Upon inquiry I learned that the name of Dr. A. E. Venables had inadvertently been left out of the list which had been handed me.

Secondly, I described the influenza outbreak of 1917 as more vicious and destructive than any epidemic of modern times. One of your editors substituted the word "insidious" for "vicious." It was not at all insidious. We had ample warning that it was coming but we could do nothing to prevent it.

Thirdly, on page 677, the paragraph at the right, above, should read, "Of the twelve physicians whom we honor this year, there are some whom, alas, I know very slightly or not at all, but about whom I have heard glowing reports, both personally and professionally."

Finally, on page 675, right, above, I had written, "if some of us interns were a little awkward and lacked *panache* the girls didn't seem to mind." The word "panache," as you know, means literally a plume or bunch of feathers, as an ornament on a helmet. It also implies dash or verve, like a knight on a white charger. In contemporary usage, a near-miss as a synonym would be "glamour," but they are not identical in meaning. Really, it should not be necessary for me to have to insert the term "(sic)" after every word at which I fear for my etymologic* life.

Well, somewhere along your editorial line someone extracted "panache" and inserted "skill." Sir, in behalf of my classmates and myself, I object strenuously to your revelation of our amatory inadequacies at that tender age, however justified these charges may be. Darn it!

Virgil J. Schwartz, M.D.
Minneapolis, Minnesota

EDITOR'S NOTE: — *Decked out with an "abacus" and a "panache," I am sure that any man, in this non-Grecian-French romantic era, could cut a great figure and would need no "etymologic" explanation to convince the object of his amour of his good intentions. We apologize for the deletions.*—C.O.R.

The Editor's Soliloquy

Professional Common Sense

If it seems right, there is a strong probability that it is; if it doesn't seem right, there is an equally strong probability that it isn't. To so conclude without a plethora of substantiating evidence is what might be called common sense—a term that might well be considered a misnomer, since common sense belies its name by being rather rare.

It is difficult to pinpoint the qualities that go to make up an individual who seems to possess this uncommon quality; but all of us are aware of having known such persons. They have the ability to sift facts from opinion, distinguish the pertinent from the irrelevant, the major from the minor; they are immune to delusion and wishful thinking as well as to unwarranted projection and extrapolation.

In the practice of medicine some physicians seem to require an overabundance of laboratory data, whereas others demand none. In the midspectrum between these two approaches is the physician whose excellent clinical judgment impels him to make only those few additional studies required to substantiate his tentative diagnosis, but whose humanistic attitude, on the other hand, impels him to consider a host of other items, clinically extraneous but most significant in the elusive correlation between the patient per se and his disease. With imagination and insight such a doctor takes into account such basically unrelated items as patient apprehensions, responsibilities, employment, expenses, and the little worries that afflict most everyone—the total framework wherein the patient must be evaluated.

Whether the doctor resolves his patient's personal problems or not, at least by sharing them he lightens them for the patient and his family—a creditable achievement in any context. Such a doctor is more interested in prognosis than in diagnosis, more concerned with probable morbidity than with a remotely possible mortality, more occupied with the emotional adjustment of the patient than with the etiology of his disease, and more cognizant of his patient's physical welfare than he is of the tedious details of the hospital record.

This is what might be called professional common sense.

Carl O. Rice, M.D.

Old Doc Hess Says: After two or three husbands a woman can, if cautious, accumulate a fairly sizable bank account.—COR

Non-Sequitur

Exercise

Whenever I feel like exercise, I lie down until the feeling passes.

—Robert Hutchins

Life-saving words. Required by Congress to appear on all packages of cigarettes.

Unquestionably an important step forward in the dramatic battle to decrease the mortality and morbidity from cigarette smoking.

But in the nation's efforts to reduce death and disease related to cigarette smoking, the most significant influence—the key figure—is you, doctor. The advice of the physician in matters of health is more authoritative and persuasive than that of anyone else.

In the area of cigarettes and health, the importance of the physician's attitude and his *personal action* cannot be overemphasized. That he has indeed taken personal action is indicated by the impressive statistic showing that only 30% of the doctors in America are cigarette smokers today!

The American Cancer Society's concerted educational campaign on the hazards of cigarette smoking—plus government regulations—will be major factors in guiding each person's approach to this problem.

But in the final analysis, doctor, it is *your* words that your patients will heed. It is you who have the best chance of actually helping an individual to stop smoking or to prevent him from starting.

Caution: Cigarette Smoking May
Be Hazardous to Your Health

AMERICAN CANCER SOCIETY

The Viewing Box

Dyspnea in a Fifty-Three-Year-Old Female

THIS 53-YEAR-OLD white female was seen in the emergency room on February 21, 1967. Her chief complaint was dyspnea of one day's duration. In addition she stated that she had had "a cold and hoarseness" for about one month. She had no sputum production and a normal temperature. Her blood pressure was 170/70. On physical examination the patient appeared to be older than her stated age; the examination was otherwise normal.

This patient has been treated for ten years for hypertension and urinary tract infections. In 1961, a unilateral nephrectomy was performed for a calcified cyst. Blood chemistries done in October 1966 included a uric acid of 8.6 mg. %, BUN of 74 mg. % and creatinine of 8.2 mg. %. The diagnosis is now chronic pyelitis and pyelonephritis with end-stage kidney disease.

Radiographic examination (Figure) demonstrated a normal sized heart with the hilar and peripheral changes of pulmonary edema. Also noted were Kerley's "B" lines which are indicative of chronic lymphatic congestion. No frank pleural effusions were present.

Figure

What is your diagnosis? (See next page.)

Diagnosis: Pulmonary edema secondary to chronic renal failure.

Discussion

With the finding of a normal-sized heart with a pulmonary hilar "butterfly" picture, with or without pleural effusion or Kerley's "B" lines, a differential diagnosis would include:

1. Over-hydration via fluids and blood.
2. Drowning.
3. Inhalants—toxic agents, hydrocarbons, etc., and oral ingestants—kerosene.
4. Elevated BUN (chronic renal failure).
5. Acute myocardial infarct with failure.
6. Pericarditis.
7. Periarteritis.
8. Carcinoid.
9. Pheochromocytoma.

It was felt that this radiographic picture was due to chronic renal disease rather than hypertensive cardiac disease, since the severity of the renal disease had increased, as supported by the laboratory studies. In addition the blood pressure remained only slightly elevated, and the heart size remained within normal limits.

Medical Seminar

Irradiation and the Fetus

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

THE PROBLEM OF irradiation and the fetus not only involves the effects of radiation on the fetus but also includes the complexities of population genetics. Man is exposed to many sources of radiation (Table 1), and from each source he receives a certain estimated dose of radiation. Natural or background radiation, which varies with locality, is estimated to provide 100 to 150 milliroentgens per year to the gonads.^{1,2} Thus the gonadal dose of radiation received from background radiation by the average individual by age 30 years is in the range of 3.0 to 4.5 roentgens. Among the sources of artificial radiation to which man is exposed, by far the most significant is the medical use of x-rays, which has been estimated to contribute a gonadal dose of 3.0 r. to the average person by the time he is 30 years old. Thus, the amount of irradiation received by the population in general from the medical use of x-rays is about equal to that received from all sources of natural radiation. The estimated 30-year gonadal dose received from radioactive fallout from nuclear weapons testing is about 0.5 r.

Radiology has been employed in obstetrics for a number of clinical situations: (1) investigation of possible cephalopelvic disproportion, either antepartum or intrapartum; (2) determination of fetal maturity; (3) determination of fetal position, when clinical findings are inconclusive or suggestive of an abnormal position; (4) determination of placental localization, when there is bleeding during late pregnancy or prior to amniocentesis; (5) investigation of excessive uterine enlargement, and (6) investigation of suspected fetal anomaly or confirmation of fetal death. In addition to these obstetric indications, roentgenography may be indicated for the inves-

tigation or work-up of any medical condition occurring coincidentally during pregnancy.

Diagnostic Procedures During Pregnancy

Common Diagnostic Procedure

In any consideration of the radiation doses involved in various diagnostic procedures, there is one fundamental concept, namely, that radiation exposure during pregnancy always involves both genetic and somatic effects by virtue of simultaneous exposure of both maternal and fetal gonads; partial somatic maternal exposure; and partial- or total-body irradiation of the fetus.

In regard to the diagnostic x-ray studies most commonly performed during pregnancy, exclusive of pelvimetry or placental localization, investigators have reported various doses to maternal

TABLE I
Sources of Radiation to Man

Natural radiation (background radiation)
External sources include cosmic radiation and radiation from naturally occurring radioactive substances (uranium, thorium, actinium, and so forth)
Internal sources include naturally occurring radioactive elements which are deposited or incorporated in the body (⁴⁰ K, ¹⁴ C, ²²⁶ Ra, and so forth)
Artificial radiation
Radioactive waste from atomic industry
Radioactive fallout from nuclear explosions and testing
Occupational exposure of certain workers such as physicians, particularly radiologists, dentists, atomic energy workers, users of radioactive isotopes
Medical use of x-rays for detection, diagnosis, and treatment of disease
Miscellaneous group of radiation emitters, such as TV receivers, watches with luminous dials, x-ray units for shoe fitting

Continued

and fetal gonads (Table 2). The considerable variation between some of these doses for the same examination depends primarily on the particular x-ray technique and routine used by each investigator. The explanation for the difference between the data of Osborn and Smith⁷ for dosage to fetal gonads in comparison to those dosages measured by the other investigators to maternal gonads for the same examination is due to the formers' assumption that if the fetal gonads were exposed only to scatter radiation, the dose would be the same as that to the maternal ovaries. If, however, the fetal gonads are exposed directly to the central beam of x-rays, the dose received would be the geometric mean between the dose to the maternal ovaries and the dose to the maternal skin.⁷ Notably, more than 80% of the genetically significant gonadal irradiation that results from roentgenography is produced by radiation secondary to the five examinations listed in Table 2, plus pelvimetry.

Radiation Secondary to Pelvimetry

With respect to radiation secondary to pelvimetry, numerous studies have been made to assess the amount of irradiation to maternal and fetal gonads. Despite the various techniques used to calculate gonadal doses, such as implanting ionization chambers in phantoms or cadavers or measuring the dose delivered to the posterior vaginal fornix, considerable variation in the dosages obtained has resulted (Table 3). Some authors^{4,11} have simply stated that the maternal gonadal dose from pelvimetry varies from 2 to 4 r., whereas the fetal gonadal dose ranges from 0.50 to 7.0 r.

There are certain other generalities regarding pelvimetry with which most investigators are in complete agreement. First, the use of high-kilovoltage techniques, high-speed intensifying screens, high-speed films, better filtration, and shielding can substantially reduce gonadal doses.

TABLE 2
Gonadal Dose from Diagnostic X-Ray Procedures (in Milliroentgens)

Fetal total body		1.2	—	—	1-3

Second, the inlet view of the pelvis, which is generally taken in the Thoms position, contributes about two thirds of the total dose of radiation from a standard, three-film pelvimetry series.⁸

Davis and Hunt¹² described the rationale behind the two-film pelvimetry technique used at the Mayo Clinic, in which one view is an inlet view of the pelvis taken in the Thoms position and the other a lateral view of the pelvis taken in the standing position. Only if a midplane contraction is found on both films is an outlet or subpubic arch view taken. Thus, by performing the outlet view only as an additional study when clinically indicated, they estimate that the total dose of irradiation received is reduced about 30% from that obtained with a three-film technique.

Radiation Secondary to Placental Localization

Ever since Browne¹³ reported the use of radioactive sodium for the first isotope placental localization in 1951, extensive work has been done in this field in an effort to decrease irradiation, provide greater accuracy, and find the ideal tracer substance for this examination. The basic requirements for a suitable radioactive material for placentography include a sufficiently long half-life to facilitate its storage, a short enough half-life to decrease radiation dosage, and reduced beta-particle emission to further decrease tissue irradiation. In addition, the tracer should be retained in the vascular compartment long enough for completion of the test but excreted rapidly thereafter to minimize radiation.

The characteristics of the most commonly used isotopes for placentography are summarized in Table 4.

The amounts of maternal gonadal, fetal gonadal, and fetal thyroid irradiation received from isotope placentography have been described by various investigators and have been compared with doses received from conventional, soft-tissue, x-ray placentography (Table 5).

Effects of Radiation on Embryogenesis

The earliest animal work in the field of experimental irradiation was concerned chiefly with the production of abnormalities. Job and co-workers,¹⁷ in 1935, while studying the effects of irradiating rats at different times during gestation, produced specific abnormalities or deformities, depending on the gestational age at the time of irradiation. They thereby advanced the concept of "critical periods" in the development of the embryo as a whole or for certain of its organs or systems, during which time irradiation would produce specific defects. In 1950 Russell¹⁸ demonstrated that these critical or susceptible periods of development for a given organ or organ system could be lengthened by increasing the dose of x-rays administered. Brent,¹⁹ in 1960, proved that it was the direct irradiation of the fetus which induced teratogenesis rather than placental injury or maternal metabolic dysfunction that affected the fetus secondarily. Otis,²⁰ in 1949, plotted more than 80 cross-reference points between the embryonic development of the human and mouse and obtained a remarkably smooth curve, thus indicating the theoretic possibility of predicting the critical period for production of abnormalities in man. All abnormalities studied in the human had critical periods that occurred between the second and the sixth postconceptional week—at the time of major organogenesis²¹ (Figure).

Continued

The most radiosensitive stage in the life history of a cell is during its transformation from the embryonic to the adult stage. During the embryonic period, 18 to 38 days after conception, such transformations are occurring in nearly every one of the tissue varieties in the human embryo.²² Thus, it was presumed that irradiation, at a time of rapid growth rate, DNA replication, cell division, and differentiation, caused the variety of effects seen during the early post-conceptional period.

Other investigators^{23,24} working with mice discovered that irradiation after fertilization, but prior to implantation, was followed by an "all or none" response to the radiation. Results of these studies showed a high incidence of prenatal death, in many series as high as 80%,²³ whereas the surviving embryos were apparently normal²¹ (Figure). However, irradiation after completion of organogenesis resulted in minimal prenatal mortality and marked reduction in detectable malformations²¹ (Figure).

Finally, the likelihood of producing neonatal malformations in the human probably is minimal if the dose of irradiation is less than 10 to 20 r. Currently, there is no experimental or clinical evidence that radiation dosages of the order involved in routine diagnostic x-ray studies, exclusive of certain high-dose fluoroscopic procedures, will produce neonatal malformations in the hu-

man.

Irradiation During Pregnancy

The best studies of radiation therapy during pregnancy are those reported by Murphy,^{25,26} Goldstein and Murphy,²⁷ and Jones and Neill.²⁸ Murphy,²⁶ in 1929, reported the outcome of 625 pregnancies in which the mother was exposed to pelvic radium or roentgen therapy either before or after conception. His study showed that irradiation before conception resulted in 0.9% stillbirths, 3.2% fetal deaths and 1.7% deformities, whereas irradiation after conception resulted in 0.0% stillbirths, 6.7% fetal deaths, and 33.7% deformities.

Goldstein and Murphy²⁷ reported a series of 75 infants born to mothers who had received therapeutic doses of pelvic radium or roentgen therapy during pregnancy for conditions such as uterine myomas, metrorrhagia, and pelvic neoplasms. Of the 30 infants (40%) who were affected by the irradiation, 70% had abnormalities of the central nervous system, the most common of which was microcephaly. Furthermore, 24 of the infants (80%) who sustained irradiation injuries had been exposed during the first trimester.

Jones and Neill,²⁸ in 1944, presented statistics from radium treatment of carcinoma of the cervix during pregnancy. Their results closely cor-

Figure

Incidences of prenatal and neonatal deaths and of abnormalities at term after irradiation of mice at various intervals. The corresponding estimated chronology for man is shown. (Reproduced with permission from Brill, A. B., and Forgetson, E. H.: *Radiation and Congenital Malformations*. Amer J Obstet Gynec 90:1149, 1964.)

roborated Strauss²⁹ earlier work in that both studies revealed the risk of microcephaly to be about 20% after therapeutic pelvic irradiation during pregnancy.

The effects of the atomic bomb explosions on pregnant females offer further confirmatory data to the previously mentioned animal and human studies. Of the 205 women who were in the first trimester of pregnancy at the time of the Hiroshima explosion, 33 delivered microcephalic infants. As would be expected, the majority of these patients were in the early part of the first trimester of pregnancy when exposed. Also, in most of the instances, the mother was located 1.5 to 2.0 km. from the hypocenter of the explosion, where the average radiation was estimated to be about 100 rads.³⁰

More recently, epidemiologic studies have provided further information regarding the long-range effects of irradiation on the fetus. Although there still is conflicting evidence in the literature, it appears that both high- and low-level doses of radiation may be capable of producing malignancy or leukemia, presumably because of chromosomal abnormalities induced by the radiation. Evidence supporting the influence of high-dose radiation in the production of malignancy or leukemia is obtained from the Atomic Bomb Casualty Commission's report of increased incidence of leukemia among the survivors of Hiroshima and Nagasaki,³¹ as well as from the increased incidence of thyroid cancer noted after irradiation of the thymus in infants so treated for thymic enlargement.³²

What are the effects of low-dose radiation, specifically those from diagnostic x-rays, and what is the etiologic relationship of such radiation to malignancy or leukemia? Stewart and associates,³³ in 1956, in a large retrospective study done in England, found what they believed was a definite causal relationship between prenatal abdominal x-ray examinations and the subsequent development of malignant disease in the children born of these pregnancies. In 1958 Stewart and co-workers³⁴ published an expanded series in which they reversed their original opinion and concluded that diagnostic irradiation did not account for the recent increase in childhood malignancy. Court Brown and associates,³⁵ in 1960, collected follow-up data on nearly 40,000 children whose mothers had received diagnostic radiation to the abdomen or pelvis during preg-

nancy and found no causal relationship to the incidence of leukemia. In 1962 MacMahon³⁶ published the most extensive report in this field. Working with a control population of nearly 750,000 children, he found that: (1) the incidence of prenatal x-ray exposure in the control group was 10.6%; (2) the incidence of prenatal x-ray exposure in children who died from cancer or leukemia was 15.3%, and (3) the mortality from leukemia was 40% higher in those irradiated in utero than in the nonirradiated control group.

At present the evidence seems to favor the hypothesis that low doses of radiation from diagnostic x-ray examinations may be leukemogenic to the developing fetus.

Genetic Effects of Radiation

The tremendous amount of work that has been done on the genetic effects of radiation since Muller³⁷ first reported the mutagenic action of radiant energy in 1927 has led to the development of certain basic precepts in radiation genetics.

1. There is no threshold dose of radiation required to produce genetic mutations. Rather, the genetic damage produced by radiation is cumulative over the years. This concept is referred to as the linearity response.

2. The effect of radiation is to increase the number of spontaneously occurring mutations rather than to produce new types of mutations.

3. Genetic mutations are almost always undesirable in that they produce deviations from normal which then continue to be duplicated and passed to succeeding generations.

4. Genetic mutations may be recessive, intermediate, or dominant, but regardless of what they are, they generally result in decreased longevity, increased susceptibility to disease, and decreased fertility.

5. Only a fractional portion of induced genetic effects will be manifest in the first post-radiation generation. With each successive generation, more expression of the genetic effect will be apparent.

6. The doubling dose concept is the amount of radiation necessary to produce the same number of mutations which occur spontaneously in a given time. For man, the doubling dose has been estimated to be in the range of 30 to 80 r., probably about 50 r.

Continued

7. Further knowledge in the area of radiation genetics is being derived primarily through the use of cytogenetic techniques.

Medicolegal Aspects of Prenatal Irradiation

Recent developments in legal precedence make it mandatory for all practicing physicians to exercise maximal prudence in their use of radiation. Currently the law is tending to acknowledge the legal existence of the fetus or embryo from the time of conception onward, on the grounds that the conceptus has an independent existence except for sustenance and protection provided by the mother. The law already protects the unborn child's property rights and grants it protection under criminal law.³⁸ The basic legal problem involved in prenatal irradiation is the establishment of a causal relationship between the radiation exposure in question and the alleged effect thereby produced.

More recently, recovery of damages has been allowed for mental distress on the part of an exposed expectant mother because of her fear of having a defective child after irradiation, despite the fact that her infant was normal at birth.³⁸ Thus, by precedence, the physician may be held liable for the expectant mother's mental anguish over the fear for the intactness of a conceived but as yet unborn child.

Some standards and recommendations have been proposed relative to radiation protection of the population in general and more specifically in the management of the obstetric patient. The Genetics Committee of the National Academy of Science recommended that for the general population the average gonadal exposure should not exceed 10 r. prior to age 30, whereas for a given individual the accumulated gonadal exposure dose should not exceed 50 r. by the time a person reaches the age of 30 years.¹ Neither of these recommendations, nor those expressed by the

International Commission on Radiological Protection,³⁹ provides for the inclusion of the amount of radiation contributed by the use of x-rays for medical diagnostic or therapeutic purposes. Instead, no specific controls or limits were established in this area intentionally, as it was believed that this represented a medical determination, and hence is best left to the prudent, informed judgment of the individual physician.

With specific reference to the use of diagnostic x-rays in women of childbearing age, most sources concur with the recommendations of the International Commission on Radiological Protection.³⁹ During the period of maximal radiosensitivity of the embryo, which is between the second and the sixth week after conception, most women are not aware of the possibility of their being pregnant. Therefore, it was recommended that, whenever possible, x-ray examinations of the abdomen or pelvic areas in women of childbearing age should be performed only during the first 10 days after a regular menstrual period that is of normal intensity and duration. As with so many other decisions in medicine, the physician must balance the probability of the benefits derived by his actions against the possibility of harmful effects to the patient.

Summary

The pregnant female is exposed to both natural and artificial sources of radiation. Important sources of artificial radiation to the obstetric patient are diagnostic x-ray procedures such as those of the chest, spinal column, kidney, abdomen, and pelvis; radiation secondary to pelvimetry; and radiation secondary to placental localization. Radiation does affect embryogenesis and has been associated with various fetal malformations. Irradiation during pregnancy must be carefully considered both from the clinical and the medicolegal viewpoint, prior to its utilization.

The more intelligent a man is, the more originality he discovers in men. Ordinary people see no difference between men.—Pascal

Clinical Path Conference

Cyanosis, Polycythemia, and Sudden Death in A 42-year-old Man

A 42-YEAR-OLD married laborer entered St. Barnabas Hospital on January 13, 1967. He complained that he was short of breath and that his legs were swollen. Although his respiratory difficulties grew worse just before he was hospitalized, he said he had had "trouble breathing" since he was ten years old. This, however, had not incapacitated him. He had served two years in the Navy, sired four children, worked on a loading dock for a wholesale firm, held down other jobs requiring physical effort, and continued to smoke three packs of cigarettes a day.

When questioned further, he said his ankle edema had slowly increased during the previous three months. But what really bothered him, he added, was an urge to sleep. His sleeping habits caused problems at work and at home. Frequently he fell asleep while in the bathroom and would awaken only when roused by his wife or another member of the family.

He was first aware of difficulty breathing when a ten-year-old youth in California. When he was thirteen, he saw a doctor because of an episode of rapid heart beat. Later, in his 20's, another doctor informed him he had an arrhythmia, digitalized him and, when the patient had bouts of tachycardia, placed him on quinidine. Despite this history, he passed the physical examination for the Navy and served two years. According to the patient, Navy physicians never told him that he had any specific disease or that he had a heart murmur.

The patient first came to St. Barnabas in 1964 while on vacation from California. He was seen in the outpatient department because of a fast heart rate, and an electrocardiogram showed paroxysmal tachycardia with right bundle branch block. He was given six grains of quinidine every two hours and converted to a regular rhythm. Then he was maintained on digitalis for two years before he discontinued the drug of his own accord.

Despite his health problems, he worked steadily. He lifted 100-pound bales of twine during the day and drove a snow plow at night. He continued both jobs until a week before he was admitted. Then ankle edema, fatigue, dyspnea on exertion, and finally shortness of breath while sitting or lying in bed forced him to come to the hospital.

Physical Examination

He was a mildly cyanotic muscular male who breathed heavily and complained of headache. His pulse was 105, respirations 48, temperature 100, blood pressure 130/70, and weight 238 pounds. Crepitant rales were detected at both lung bases. Different examiners could hear no heart murmurs. The fingers showed no clubbing. The liver and spleen were not palpable. The lower legs, which were swollen and showed a taut glistening skin, pitted when pressed. The physician

Continued

who admitted the patient diagnosed congestive heart failure and, because the patient was a big man with a history of somnolence, also suggested Pickwickian syndrome.

Laboratory Data and Course

A circulation time done the day he was admitted was 24 seconds. He was then rapidly digitalized and put on a low-sodium diet. The first blood work included a hemoglobin of 18 grams percent, a hematocrit of 63 percent, a wbc. of 10,400 with 80 polymorphonuclear leucocytes and 10 band forms, and a platelet count of 255,000. The blood urea nitrogen was 11 mg./100 ml., the cholesterol 195 mg./100 ml., and the serum electrolytes normal.

During his first three hospital days, he quickly lost 20 pounds and his edema subsided. Because of his polycythemia, 500 ml. of blood was removed from his arm. Although his headache abated, he remained cyanotic and his heart continued to fail.

On January 17, four days after admission, he became apneic. He was resuscitated, but his breathing was shallow and rapid. A pH. was 7.46, and the carbon dioxide content was 37 mcq/l. An anesthesiologist tried to improve his respiratory exchange by giving oxygen under 25 mm. of water pressure. When the patient failed to improve, the anesthesiologist increased the pressure to 40 mm. of water. Again the patient stopped breathing. This time he did not respond to resuscitative measures.

Discussion

Dr. Donald Bohn:*

Before I discuss this patient's story, could I see the x-rays?

Dr. Philip Olson:**

Films of the chest taken on January 13 and 17 show prominent vessels in both lung fields. His diaphragms are high, and he obviously has no emphysema. I see no edema or congestion. The heart is transverse. His left heart does not appear hypertrophied, but his right heart border extends more to the right than usual. I don't have a lateral film to see whether his right ventricle bulges, but his right heart looks big.

The proximal two thirds of the lung vessels are dilated but then disappear peripherally. When I see a film like this, I think first of an acute coronary with slight heart enlargement but without pulmonary edema. I cannot make out septal lines, but I note some basilar atelectasis, presumably due to high diaphragms and lack of excursion. With this patient's history of pulmonary resistance, I would consider pulmonary fibrosis, pulmonary hypertension (primary or secondary), and right heart hypertrophy with failure.

Electrocardiograms

This patient had two electrocardiograms while he was in the hospital. The admitting cardiogram showed right axis deviation and nonspecific ST wave changes. Four days later, the day he died, the pattern changed profoundly. Though he had received digitalis, the right axis deviated more to the right, and

*Attending Internist and Coordinator in Medicine, St. Barnabas Hospital.

**Radiologist, St. Barnabas Hospital.

the cardiogram disclosed more right ventricular strain. Neither of the tracings shows arrhythmias.

Differential Diagnosis

This man presented with heart failure, a prolonged circulation time, massive edema, and polycythemia with a hematocrit of 63 percent. He slept often, sometimes at embarrassing moments. He had no cough or murmurs, yet he deteriorated rapidly, stopped breathing, was resuscitated with the help of positive pressure breathing, and then died.

Immediate Cause of Death

First, let me dispense with the immediate cause of death. I think he had a pneumothorax. The oxygen had to be given at extremely high pressure, in this case 40 mm. of water, to overcome his pulmonary resistance. Since the lungs cannot withstand this amount of pressure long, I postulate a terminal bilateral pneumothorax.

Pulmonary Hypertension and Emphysema

What interests me most about this man is that his lung problems existed for over 30 years. Finally, his lung disease caused his heart to fail. Probably he had some type of pulmonary hypertension with right heart failure as a climactic event. Why pulmonary hypertension? He had polycythemia, apnea, characteristic x-rays, and right ventricular strain on the cardiogram. The usual cause for all of this is, of course, emphysema.

Obstructive emphysema produces pulmonary hypertension in different ways. Anoxic episodes play some role and so does fibrosis. Yet, though this man smoked three packs of cigarettes a day, his chest films show no emphysema.

Congenital and Acquired Heart Disease

Another group of disorders which can give rise to pulmonary hypertension includes congenital heart disease with shunts. He served two years in the Navy and was hospitalized to evaluate a tachycardia. It is unlikely that a man with congenital heart disease could slip by a team of Navy doctors without having a murmur detected. Also different examiners at St. Barnabas heard no murmur.

Acquired heart disease, such as mitral stenosis, can also produce pulmonary hypertension. Again the absence of murmurs effectively excludes this as cause of his problems. Certain facets of his illness, however, fit with mitral stenosis. These include paroxysmal tachycardia, pulmonary hypertension, and intractable failure. Also these patients have rales, become dyspneic and orthopneic, and can't lie down at night. But such symptoms are chronic and insidious in mitral patients, and this man didn't really get into trouble until the last week of his life. Then suddenly he went into complete right heart failure and never came out of it.

There are other rare disorders, such as *cor triatriatum*^{*}, which can act like this. But again most of those diseases produce murmurs, for shunts that give rise to cyanosis have murmurs.

Now I am approaching what I think this man had—primary pulmonary hypertension. What is primary pulmonary hypertension? Is it a disorder which is inherited? Is it the result of multiple pulmonary emboli? Patients with emboli can develop both pulmonary hypertension and heart failure.

The difficulty with that theory is that our patient's symptoms started when he

Continued

^{*} See Test Your Word Score Page 1227.

was ten. Pulmonary emboli starting at ten in a man who worked as a laborer, who never had phlebitis, and who never coughed up blood are, in my opinion, unlikely. His course is more in keeping with primary pulmonary hypertension. He has the x-ray findings, the electrocardiographic changes, and the usual course. When he finally decompensated, he failed to respond to all measures.

In primary (or unexplained) pulmonary hypertension, patients are typically young. Their symptoms may start when they are four to six years old. But the usual onset of symptoms is in the third and fourth decade. The disease occurs in women four times more often than in men.

Polycythemia

That this patient was a man does not disturb me, but I find the elevated hemoglobin and hematocrit hard to explain. In theory, patients with primary pulmonary hypertension do not become polycythemic. But our patient suffered from anoxia for the last three months of life, probably even longer. Anoxia causes polycythemia, and I attribute his high hemoglobin and hematocrit to anoxia.

When a man with primary pulmonary hypertension becomes anoxic, his pulmonary arteries and arterioles constrict, the hypertension in the lesser circuit increases, and his vessels constrict still more. Once this cycle starts, it does not revert, and the patient goes on to fulminating death. Such a chain of events—pulmonary hypertension polycythemia, and sudden death—sometimes occurs in Peruvians who live at high altitudes.

The protocol does not list enough blood gas chemistries for me to discuss acid-base problems. He may have had a chronic CO_2 retention, but I doubt if he had the Pickwickian syndrome. That usually occurs in patients who are massively obese. This man was muscular, heavy, and edematous—not obese. He undoubtedly had respiratory acidosis and probably a carbon dioxide narcosis before he was given intermittent positive pressure breathing. When the machine began to exchange oxygen, readily diffusible carbon dioxide washed out, and a normal pCO_2 resulted. That he did not breathe on his own is good evidence for carbon-dioxide narcosis. His respiratory center failed to respond.

I am left with diagnoses of primary pulmonary hypertension, right ventricular hypertrophy, and pneumothorax.

Dr. Donald Bohn's Diagnosis

Primary Pulmonary Hypertension
Right Ventricular Hypertrophy
Pneumothorax

Discussion

Dr. William Renti-Cruz:*

If you suspected pulmonary hypertension, couldn't you document it by catheterizing the pulmonary artery?

Dr. Bohn:

Yes, but it's risky. These people die when you put a catheter in their pulmonary artery. Their vessels constrict further, they get arrhythmias, and they die. A catheterization would show normal wedge pressure, but a high pulmonary artery pressure.

*Intern, St. Barnabas Hospital.

Dr. Ramesh Kharwadkar:[°]

What about an angiogram?

Dr. Bohn

An angiogram would show a hypertrophic right ventricle, a dilated pulmonary artery, and large vessels disappearing at the periphery.

Dr. Liborio Liro:^{°°}

Could this be Ayerza's syndrome?

Dr. Bohn:

As far as I am concerned, this is Ayerza's syndrome. In 1901 Ayerza described a condition characterized by slowly developing bronchitis, dyspnea, cyanosis, and polycythemia. It is a primary disease of the pulmonary artery and its branches and has the same pathological findings as primary pulmonary hypertension.

Pathological Discussion

Dr. Richard Reece:[†]

Doctor Bohn hit the nail on the head. This man did have primary pulmonary hypertension with a pneumothorax. When I entered the chest cavity, air gushed

Continued

forth, and his diaphragms suddenly deflated. Although I looked for the precise source of his pneumothorax, I could not find it. I observed intact pleural blebs, but none were ruptured.

The right lung weighed 1000 grams and the left 550 grams. Though the lungs showed atelectasis, some lobes were consolidated and did not collapse. All lobes displayed a watery cut surface with froth exuding from the parenchyma and the bronchi. Microscopically, swarms of polymorphonuclear leucocytes crowded many alveolar spaces; the rest of the alveoli showed pulmonary edema and "heart failure" macrophages.

The pulmonary artery was dilated and sclerotic. Buttery arteriosclerotic plaques raised the intimal surface. Under the microscope, smaller pulmonary arteries and arterioles disclosed intimal endothelial proliferation, medial hypertrophy, and prominence of elastic laminae (Figures 1 and 2). These are the changes usually described in primary pulmonary hypertension.

The heart weighed 540 grams, and the right heart was hypertrophied and dilated. The wall of the right ventricle was more than one cm. thick. All the valves were delicate, and the coronary arteries were free of arteriosclerosis. The liver showed the changes of long-standing chronic passive congestion.

Final Anatomical Diagnoses

1. Dilatation of pulmonary artery with arteriosclerosis; intimal proliferation and median hypertrophy of pulmonary muscular arteries and arterioles (primary pulmonary hypertension)
2. Cardiomegaly (540 grams), right ventricular hypertrophy
3. Bilateral bronchopneumonia
4. Pleural blebs with bilateral pneumothorax (possibly secondary to intermittent positive pressure breathing)
5. Passive congestion of liver.

Norman Code of Licensure (1140)

Who, from now on, wishes to practice medicine, has to present himself before our officials and examiners, in order to pass their judgment. Should he be bold enough to disregard this, he will be punished by imprisonment and confiscation of his entire property. In this way we are taking care that our subjects are not endangered by the inexperience of the physicians.

Nobody dare practice medicine unless he has been found fit by the convention of the Salernitan masters.

Editor's Note: Are our standards becoming less severe?

Books vs. Pictures

How much better it is to have the walls covered with books with which we are establishing friendly relations, than with pictures of passing interest which we happened to obtain. Eventually pictures lose their interest, whereas books never lose their fascination.—William Mayo

Cloxacillin for Prophylaxis in Oral Surgery

DANIEL E. WAITE, D.D.S.*
ALEXANDER SCHIRGER, M.D.**
WILLIAM J. MARTIN, M.D.**
Rochester, Minnesota

MEMBERS OF OUR group have previously reported data on the use of phenoxymethyl penicillin and erythromycin for the prevention of post-operative bacterial invasion of blood after oral surgical procedures.¹⁻³ In a continuation of these studies, sodium cloxacillin monohydrate, a penicillinase-resistant semisynthetic penicillin, was used. It is generally agreed that cloxacillin gives serum levels twice as high as oxacillin, when equal amounts of the drugs are given orally.⁴ The purpose of this study, as it has been with the others, was to test the effectiveness of the selected antibiotic agent under the conditions outlined.

Materials and Methods

The patients were selected solely on the basis of their need of oral surgical procedures. The surgical problems consisted mostly of impacted third molars and full-mouth extractions because of periodontal disease or caries or both. Sodium cloxacillin monohydrate† in capsule form was administered in four successive doses of 250 mg. beginning 18 hours prior to operation. Blood for cultures was drawn immediately after the operative procedure while the patient was still in the operating room and again approximately 18 hours later. Fifty-two patients were studied and no patient was included who had either pre-existing or known infection, valvular heart disease, or a combination of these problems. Ten of the 52 patients had positive cultures from the blood obtained immediately after the surgical procedure. As is apparent from the Table, cul-

tures of blood from nine of the 10 patients were negative 18 hours after operation. Cultures of blood from one of the other two patients showed an aerobic sporeformer in liquid medium only and cultures from the other patient showed *Streptococcus mitis*.

Comment

It is noteworthy that blood cultures in eight of the 52 patients yielded *Streptococcus mitis*. In seven cases, organisms were grown in samples of blood obtained immediately after operation; in the eighth case, blood was obtained 18 hours after operation. This high incidence approximates that encountered in one of our previous studies, wherein 50 patients did not receive any antibacterial agent before operation.¹ It stands in sharp contrast to our experience with patients who have received optimal amounts of phenoxymethyl penicillin^{1,3} or erythromycin⁵ before operation and in whom cultures for *Streptococcus mitis* have been consistently negative. The finding was not anticipated prior to the study, since cloxacillin is generally considered effective against streptococci of this variety. As a matter of fact, we had concluded a priori that the effect

Blood Cultures After Oral Operation With Cloxacillin

Continued

of cloxacillin would likely be similar to that of phenoxymethyl penicillin and erythromycin against most organisms inhabiting the oral cavity, and that its antistaphylococcal effect would be greater than that of these agents. However, even the latter effect is debatable, since blood cultures from two patients in the present series grew staphylococci in contrast to six of 94 patients receiving phenoxymethyl penicillin¹⁻³ and none of 42 receiving erythromycin.⁵ We chose cloxacillin rather than oxacillin because of the higher blood levels obtainable with the former drug. We are currently studying nafcillin, which results in blood levels comparable to those achievable with oxacillin, but concentrations of nafcillin appear to persist longer in blood and tissues.

From the data accumulated in the present study, it now appears necessary to give a group of patients 500 mg. of cloxacillin rather than 250 mg. and to determine the results in the manner described herein. If decreased intestinal absorption of cloxacillin were due to food ingested in the 18 hours before surgery, perhaps the increased dosage would result in higher serum levels and a more desirable antibacterial effect. In any event, we cannot recommend cloxacillin in the dosage employed in this study, in at-

tempts to prevent bacterial invasion of the blood after oral surgical procedures.

Summary

Fifty-two patients received cloxacillin in amounts of 250 mg. for four doses by the oral route beginning 18 hours before oral surgery. In 10 of the 52 patients, cultures of blood drawn immediately after operation grew bacteria. Seven of the 10 positive cultures grew streptococci of the *mitis* group and two grew coagulase-negative staphylococci. In an additional patient, cultures of blood drawn 18 hours after operation also grew *Streptococcus mitis*. These findings stand in sharp contrast to our experiences with patients who have received optimal amounts of phenoxymethyl penicillin or erythromycin preoperatively and in whom cultures for *Streptococcus mitis* have been consistently negative. Cloxacillin, in the dosage employed in this study, cannot be recommended in attempted prevention of bacterial invasion of the blood subsequent to oral surgical procedures.

Acknowledgement

The authors wish to express appreciation to G. M. Needham, Ph.D., of the Section of Microbiology for his assistance in this study.

Music and Disease

I ran across the statement very recently in the book of Theophrastus On Inspiration that when gouty pains in the hips are most severe they are relieved if a flute-player plays soothing measures. That snake bites are cured by the music of the flute, when played skillfully and melodiously, is also stated in a book of Democritus entitled On Deadly Infections, in which he shows that the music of the flute is medicine for many ills that flesh is heir to. So very close is the connection between the bodies and the minds of men, and therefore between physical and mental ailments and their remedies.

—Aulus Gellius (2nd Century A.D.)

Grand Rounds

Acute Benign Pericarditis*

ANDREW E. EDIN, M.D.
Medical Resident

THE SUBJECT of this paper is misleadingly called "benign" since, in some instances, the complications are life-threatening. The term pericarditis is pathologically too limiting because in every recognizable instance there is also myocardial involvement. Even the term "acute" is less than truthful, for frequency of recurrence is one of the common findings in the disease. Acute benign pericarditis is a non-specific form of acute serofibrinous pericarditis, which may be caused by a variety of etiologic agents. Pericarditis is, of course, an inflammation of the membranes which envelop the heart. However, the symptoms and signs and the laboratory data in acute pericarditis cannot be explained by pathology of the pericardium alone. Most of the laboratory and clinical manifestations are secondary to involvement of the lungs, pleura, epicardium, myocardium and conduction system of the heart.

One of the more common varieties of acute pericarditis is that cluster of diseases called acute benign pericarditis, acute idiopathic or acute non-specific pericarditis. None of these names is free from objection, and one author has suggested "acute perimyocarditis" as a more suitable name⁴. Acute benign pericarditis has been historically a wastebasket diagnosis. As specific etiologies for more and more forms of acute pericarditis have been delineated, the "idiopathic" spectrum has narrowed. A wide variety of forms of pericarditis, including Dressler's syndrome, post-pericardiotomy syndrome, and post-traumatic pericarditis, are very similar clinically to acute benign pericarditis and were certainly contained in the wastebasket of acute benign pericarditis at one time. The pericarditis associated with systemic lupus erythematosus was also retrieved only relatively recently.

Etiology

In the recent literature acute benign pericarditis has been attributed to either a viral infection or a hypersensitivity reaction or to combinations of both. The case for a viral etiology has been well established by numerous investigators^{17,18,19,20}.

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, January 17, 1967.

Continued

Virus

Coxsackie B, types 2, 3, 4, and 5, have been implicated in most reported cases associated with a virus. Many investigators have recovered the virus in stool specimens obtained during the illness, and by demonstrating a rise in the titer of neutralizing antibodies obtained in acute and convalescent sera. In a few cases the virus has been isolated by pericardial fluid aspiration. Other viruses implicated have been influenza A and B^{9,14}, mumps²¹, Echo type 8²¹, infectious mononucleosis¹⁵, and chickenpox. None of these viruses have any myocardial or pericardial specificity, and it is probable that any viral infection may occasionally produce acute benign pericarditis. Spink et al.⁸ stated that myocarditis complicated upper respiratory infections in 10.8 percent of cases. Another study of an epidemic of Coxsackie virus infections showed three patients out of 28 to have myocardial and pericardial involvement¹⁶.

Idiopathic

Despite the recent emphasis on viral etiology of acute benign pericarditis, many cases must still be considered idiopathic. One study reviewed 34 cases of acute benign pericarditis in which exhaustive investigations were performed in search of a specific etiologic agent, and in only five cases were viruses implicated²¹. Another series of 269 cases reported preceding upper respiratory infections in only about 30 per cent of patients³.

Anti-Heart Antibodies

There has been speculation that some cases of acute benign pericarditis may be secondary to an allergic, auto-immune, or hypersensitivity process. It has been mentioned that the syndrome of acute benign pericarditis is very similar to Dressler's syndrome and to the post-pericardiotomy syndrome. There may be an identical non-specific immunologic response due to many agents causing myocardial and pericardial injury. In Dressler's syndrome, post-pericardiotomy and post-trauma syndromes, the initial injury to the myocardium alters a myocardial protein which becomes an antigen, to which the heart develops anti-heart antibodies. By means of the indirect immunofluorescence technique and the anti-globulin-consumption test, antiheart antibodies have been detected in 13 of 15 cases of post-pericardiotomy syndrome and in eight of 14 cases of Dressler's post-myocardial infarction syndrome²². It may be that in some cases, mild viral infections have caused myocardial or pericardial injury, following which the heart develops anti-heart antibodies, but this has not been demonstrated to be the case in acute benign pericarditis. However, no thorough study has been made of a large group of acute benign pericarditis patients in an attempt to demonstrate anti-heart antibodies.

We are left with two major groups in consideration of the etiology of acute benign pericarditis: first, the viral agents, which some authors set aside as acute viral pericarditis, but which most authors lump with the "benign" or "non-specific" category; secondly, the larger, but clinically indistinguishable group of "idiopathic" etiology.

Clinical Features*Chest Pain*

Acute benign pericarditis is frequently associated with or preceded by an upper respiratory infection. The onset is usually acute, heralded by the sudden

ACUTE BENIGN PERICARDITIS

appearance of chest pain, usually substernal, of any intensity, radiating into the neck or shoulder but seldom down the left arm. However, Barnes and Burchell reported 14 cases of "acute pericarditis simulating acute coronary occlusion."²³

Epigastric Pain

Abdominal laparotomies have been performed because of the location of the pain in the epigastrium. The pain is often increased by deep inspiration and by recumbency, especially in the left lateral decubitus position. Coughing and swallowing may aggravate the pain. It is often relieved by sitting up and leaning forward. The pain in pericarditis is probably produced by either or both of the following: (1) Distention of the pericardial sac by effusion with stimulation of the only pain-sensitive portion of the pericardium, the lower parietal pericardium. This is often a dull aching pain. (2) An associated pleuritis involving the pleura adjacent to the pericardium, which would account for the sharp pain and radiation from the substernal area.¹

Fever

Fever is a frequent finding, often in the range of 101 to 103 degrees F. Dyspnea is a prominent symptom, usually manifested by a rapid respiratory rate and shallow forced respirations. The pathogenesis of the dyspnea is unknown. A pericardial friction rub is present at some time in most cases. Pleural and pericardial effusions are common. It must be remembered that although a pericardial friction rub is pathognomonic, it is by no means essential to the diagnosis. Atrial arrhythmias may occur but are infrequent.

TABLE
Clinical Data on 34 Patients with Acute Benign Pericarditis²¹
Frequency in Percent

<i>Symptoms</i>	
Pain	100
Dyspnea	32
URI	24
Nausea and vomiting	15
<i>Signs</i>	
Fever greater than 100 degrees F.	82
Pericardial friction rub	62
Tachycardia	16
Rales	15
Pharyngitis	12
Lymphadenopathy	12
Pleural friction rub	12
<i>Laboratory Results</i>	
EKG abnormalities	97
Characteristic S-T and T wave changes	79
T wave changes without S-T elevations	15
Non-specific changes	3
Abnormal chest x-rays	59
Enlarged cardiac silhouette	41
Pleural effusion	18
Parenchymal infiltrate	15
Leukocytosis greater than 10,000	59

Electrocardiogram

The electrocardiogram is frequently but not always abnormal in cases of acute pericarditis, and the changes observed are suggestive rather than diagnostic of pericarditis. Because of the non-specific nature of the changes, one cannot use the electrocardiogram in acute pericarditis to differentiate between acute benign pericarditis and other forms of acute pericarditis. The common electrocardiographic changes observed in acute pericarditis were found in 80 per cent of 57 cases in one study,¹⁰ while another group found 61 per cent of 76 cases¹¹ to have the characteristic abnormalities. Hull,¹² in an excellent symposium on pericarditis, stresses that none of the electrocardiographic changes commonly associated with pericarditis are directly due to involvement of pericardial membranes per se. It is probable that most cases which lead to changes in the electrocardiogram and in all cases where the typical changes are manifest, the process is diffuse, involving most or all of the epicardium.¹²

S-T Segment

S-T segment elevation is thought to be secondary to diffuse subepicardial myocardial injury.¹⁰ S-T segment elevation is usually the earliest electrocardiographic abnormality seen in acute benign pericarditis and often disappears with early clinical improvement. Typically an upward concavity of the S-T segment is seen, and in early cases T waves of normal form evolve from it, in contradistinction to the usual convexity of the S-T segment elevation seen in acute myocardial infarctions. Also missing is the usual reciprocal S-T depression seen in myocardial infarctions. In many cases of acute pericarditis AVR and V₁ remain unaffected.

T Wave

T wave changes are usually found later in the course, and in the more "benign" cases may never appear.¹³ Most frequently the T waves flatten progressively as the S-T segment returns to the isoelectric line. This may occur in days or weeks. T wave inversion may occur without S-T changes preceding it and, although with the passage of weeks or months the T waves usually become upright and of full amplitude, permanent inversion or diminished amplitude is not infrequent. The S-T segment and T wave may change from day to day and from lead to lead. The instability of these electrical changes is in itself suggestive of a diagnosis of acute pericarditis.

QRS Complex

In cases where a pericardial effusion complicates the picture of acute benign pericarditis, decreased amplitude of the QRS complex is frequently seen. It must be emphasized that in a considerable percentage of effusions, even large ones, there will be no diminution of the QRS voltage. In addition, low voltage is seen in a considerable number of other conditions: for example, those in which there is fluid accumulation such as pleural effusion and metabolic disorders of the myocardium. The low voltage seen with diffuse myocardial disease may closely resemble that of a pericardial effusion. Suffice it to say that the electrocardiogram plays a minor role in the diagnosis of pericardial effusion.

Arrhythmias are infrequently associated with pericarditis, but they have been noted in cases of acute benign pericarditis of viral origin.¹ The usual picture is atrial fibrillation.¹³ It may be that the superficial location of the sinus node

less than 1 mm. beneath the epicardium is a factor in the production of atrial arrhythmias.

Complications

Complications of acute benign pericarditis include effusion, with or without tamponade, hemopericardium, chronic constrictive pericarditis, and repeated recurrences, although effusion and recurrence have been reported as occurring frequently with this disease.

Constrictive Pericarditis

Chronic constrictive pericarditis is generally thought to be a rare sequel of acute benign pericarditis.⁶ Review of the literature of long-term follow-up studies on 522 patients with acute benign pericarditis revealed that six had developed constrictive pericarditis.⁵ There have been 11 reported cases of chronic constrictive pericarditis following acute benign pericarditis. Of these, six developed constriction within six months and the remainder within four years of the acute episode.⁵ It has been pointed out⁵ that studies of patients with chronic constrictive pericarditis reveal a large percentage of cases of unknown etiology. This suggests the possibility that some of these cases may have followed acute benign pericarditis. I would interpret this data to indicate that although constriction is an uncommon complication and sequel to acute benign pericarditis, it is more frequently found than has been appreciated.

Effusion

In a large study³ approximately 35 per cent of the patients developed significant effusions, a diagnosis made largely on roentgenographic evidence. In general the patients with effusion were felt to have a more severe form of the disease, as evidenced by more pain, a prolonged course, and especially the increased incidence of recurrence. There was a 40 per cent recurrence rate in patients with effusion, versus a 15 per cent recurrence rate in those patients without effusion. Another group²¹ had pericardial effusions demonstrated in 41 per cent of patients, and had pleural or pneumonic manifestations in 32 per cent. The overall recurrence rate appears to be about 20 to 25 per cent, with the higher rate expected in patients with effusion.

Cardiac Tamponade

Twelve fatalities have been reported in patients with acute benign pericarditis.⁷ In five cases, cardiac tamponade was present and was thought to be the cause of death. In four of these cases, anticoagulants had been administered and the fluid was sanguinous. The remainder of the cases were associated with various forms of underlying myocardial disease. It would appear that when acute "benign" pericarditis occurs in a patient with some pre-existing moderately severe myocardial disease, the disease is no longer "benign."

Diagnosis and Differential Diagnosis

Sodeman and Smith report only 20 per cent accuracy in the recognition and diagnosis of acute pericarditis.²⁵ As is true in so many conditions, a high index of suspicion is necessary to make the correct diagnosis. The differential diagnosis is essentially that of chest pain.

Continued

Myocardial Infarction

Myocardial infarction is the most important diagnosis to exclude because of the prognosis and therapy. This is especially important in this era of anti-coagulants. The presence of a friction rub early in the course, pericardial effusion, the nature of the chest pain, characteristic electrocardiogram changes, presence of fever and preceding or concomitant upper respiratory infection help distinguish pericarditis from myocardial infarction. The level of the serum glutamic oxaloacetic transaminase may be helpful, but increased levels may be found in pericarditis. As one might expect, the serum glutamic oxaloacetic transaminase elevation has been shown to be related to the extent of subepicardial injury rather than the magnitude of pericardial inflammation.²⁴

Pulmonary Disease

Pneumonia and pulmonary infarction are also likely to be confused with acute pericarditis. Routine work-up should include complete blood cell count, urinalysis, blood cultures, sedimentation rate, electrocardiogram, chest x-rays, skin tests for TBC and triple fungus, and viral studies.

Diagnosis of pericarditis per se is not adequate. One must rule out all of the other causes of acute pericarditis before diagnosing acute benign pericarditis. Bacterial (especially tuberculous), neoplastic, metabolic, traumatic, and allergic etiologies must be ruled out. In addition, the S.L.E., rheumatic fever group of collagen-hypersensitivity diseases must be excluded. Even if presumptive laboratory findings indicate a viral etiology, the other causes must be ruled out, since viral infections may coexist with, but not be the cause of pericarditis of another origin. Some authors urge pericardial biopsy and/or diagnostic aspiration of pericardial fluid if the diagnosis remains in doubt. Lupus erythematosus cells should be searched for diligently, especially in young females.

Treatment*Bed Rest*

Complete bed rest is the best treatment for acute benign pericarditis, and in most patients the early institution of bed rest alone results in the prompt subsidence of symptoms. Usually a total period of two to three weeks is sufficient, but bed rest should be continued beyond the time of disappearance of any friction rub. If temperature elevation or chest pain recurs, bed rest should be reinstituted. Most cases will require only mild analgesics such as salicylates; when pain severe enough to require opiates is present, it will usually be unnecessary to continue them beyond the first few days of hospitalization. Antibiotics are of no benefit in this type of pericarditis.⁴

Steroid Therapy

Corticosteroids have proven to be of particular value in the relief of pain when opiates are ineffective. They also lessen the dyspnea associated with splinting of the chest without the impairment of ventilation which may be seen with opiates. The dosage usually recommended is from 40 to 80 mg. of prednisone daily in four divided oral doses.^{1,2,4} In critically-ill patients the response is often dramatic, with relief of symptoms in less than 24 hours. When the patient is afebrile and symptom-free, the dose should be cut to 20 mg. per day and then gradually reduced over the next two or three weeks. If difficulty is encountered in termination of the course of steroids, addition of analgesics may prove helpful.

It is the impression of some investigators that steroids may decrease the formation of pericardial fluid and the likelihood of pericardial tamponade. There are no data to suggest that the course of an attack of acute benign pericarditis is shortened by steroid therapy, and the premature withdrawal of steroids often results in a "rebound phenomenon" with return of pain and fever.² It cannot be overemphasized that steroids must be reserved for those who are severely ill and do not respond to other measures. In one series of 27 patients with acute benign pericarditis complicated by recurrences, 67 per cent had good response to a regimen of steroids brief in duration and moderate in dosage. However, the remaining 33 per cent had repeated rebound phenomena associated with cessation and required up to three years for withdrawal.³ Bacterial and especially tuberculous pericarditis must be vigorously sought and ruled out before steroids are instituted. There has been no evidence that viral illness might be disseminated by steroid therapy.²

Operative Procedures

Pericardiocentesis is probably more often done for diagnostic than for therapeutic reasons, but if there is evidence of cardiac tamponade a vigorous rather than expectant course of action is indicated.¹

Pericardiectomy is usually reserved for patients with chronic constrictive pericarditis, a rare complication of acute benign pericarditis, and should be given serious consideration in the presence of recurrent pericarditis to prevent further recurrences.³

Case Report

A 21-year-old white single male, a college student, was admitted to this hospital on 9/18/66 with a chief complaint of chest pain. He dated the onset of his present illness to four days prior to admission, when he developed a "cold," sore throat, back pain, slight dysuria and increased frequency. Within 24 hours he had chills and a temperature of 103 degrees F.

He presented himself to the Hennepin County General Hospital emergency room on 9/15/66. Erythema of the throat and CVA tenderness were noted. Wbc. was 16,300 with 82 P.M.N.'s. Throat culture obtained eventually grew "normal flora." Urinalysis showed only occasional wbc.'s and was negative for albumin. Urine culture was "no growth." Despite the lack of positive findings he was treated with gantrisin for a urinary tract infection. The following day his throat was red and he was treated with I.M. Bicillin. On 9/17/66 he noted the onset of chest pain for the first time. He described it as gradual in onset, substernal, non-radiating, non-pleuritic, and lasting approximately 45 minutes, disappearing spontaneously. He denied cough or dyspnea. On the day of admission, he was awakened at 4:30 a.m. by a similar type of pain, this time accompanied by diaphoresis. Seen in the emergency room two hours later he still complained of chest pain. His temperature was 101 degrees F. Urinalysis and complete blood count were normal; sedimentation rate was 22. He was sent home but returned a few hours later because of the recurrence of very severe substernal non-radiating chest pain. He appeared pale and acutely ill; his blood pressure was 100/60. He was admitted after an electrocardiogram was obtained.

Physical examination on admission revealed, in addition, bilateral white tonsillar exudates. No pleural or pericardial friction rubs were heard. The remainder of the physical examination was within normal limits.

Hospital Course

The initial electrocardiogram showed S-T segment elevation in leads II, III, and AVF. Serum glutamic oxaloacetic transaminase obtained consecutively were 95, 53, 23, 12, and remained normal thereafter. Sedimentation rates were 22, 34, 79, 79, 21, 11, and 5. L.E. preps were negative. Heterophile titers were negative. C.b.c.'s were within normal limits throughout the remainder of the hospital course. The patient had one episode of chest pain, relieved by demerol, after admission. He became afebrile shortly after admission and

Continued

GRAND ROUNDS

remained so. Fungal and TBC skin tests were negative. By 9/20/66 the electrocardiogram showed S-T segment elevation and terminal T negativity in I, AVL and V6. By 9/26/66 the S-T elevation returned to the baseline and the T waves become more negative. The patient was discharged on 9/27/66. Discharge diagnosis: Acute benign pericarditis, viral etiology suspected, not proven.

Follow-up electrocardiogram on 10/11/66 showed negative T waves in I, II, III, AVF, V5 and V6. Follow-up electrocardiogram on 1/4/67 showed all negative T waves returned to upright position.

The Mithridaticum

Mithridates lived in constant fear of being poisoned, to overcome which, he tested a large number of poisons on criminals and prisoners of war, and took small, increasing doses of poisons and antidotes during the greater part of his life. Today we use the term mithridatism in medicine to denote the insusceptibility to the effects of poison produced by taking a series of gradually increasing doses . . . When Pompey defeated Mithridates (66 B.C.) he found the prescription for this very complex general antidote, together with other medical manuscripts with the king's body. This famous prescription became known as the Mithridaticum.

The mithridaticum was improved especially by Nero's personal physicians and its use extended to a great number of ailments. There were two principal formulas named for Nero's physicians respectively, one having fifty-five ingredients, and the other seventy-two. In Nero's time these complex prescriptions became known as Theriacs, the word being derived from the snake called tyrus, the flesh of which was added to the ingredients by Andromachus, Nero's doctor. Directions for making theriacs are to be found in all dispensaries down to those of the 19th century.*

Abstracts, Briefs and Commentaries

BREAST CARCINOMA

Goldsmith et al. have studied a series of consecutive autopsies on women who had been operated on for carcinoma of the breast. They were particularly interested in the pulmonary lymphangitic metastasis which occurred and found that approximately 25% of the post-mortem examinations reveal pulmonary lymphangitic involvement and that approximately 20% died a pulmonary death.

Not all of these pulmonary lymphangitic involvements were demonstrable by Xray. The restrictive lung disease symptoms caused by the pulmonary lymphatic metastases were evidenced in decreased tidal volume, increased rate of frequency, diminished inspiratory capacity and vital capacity, and diminished maximum breathing capacity and reserve volume. The only other pulmonary state that can give a comparable set of pulmonary function abnormalities is thought to be a radiation fibrosis.

MELANOMAS OF THE VAGINA

Melanomas are migratory marauders and can crop up anywhere in the body where melanocytes exist. About 3 per cent of vaginas have intraepithelial melanocytes, and three dozen melanomas have been reported to arise there. Norris and Taylor, pathologists at the Armed Forces Institute of Pathology, review 13 cases. The melanomas presented as soft, blue-black, bleeding masses in older women (average age 62 years). The median survival after surgery was 10 months. Ten of the 11 patients surviving more than one year died of metastases, and one still lives, more than six years after surgery. Norris and Taylor documented melanomic pigment in 11 lesions and functional change in 10. Five tumors displayed spindle cell transformation, and two were comprised of anaplastic cells indistinguishable from anaplastic carcinoma or lymphoma. Pathologists confronted with an undifferentiated vaginal neoplasm should search for pigment and functional change to make a clear-cut diagnosis. Nearly all pigmented vaginal lesions are malignant.

TREATMENT OF HYPERTHYROIDISM

In recent years the treatment of hyperthyroidism has been both surgical and medical. The medical treatment consists principally of radioactive iodine or antithyroid drugs.

Plested and Pollock of the University of California, Los Angeles, have made a comparison of the end results of surgical vs. medical management. In their studies the surgical management produced a euthyroid state in 87%, whereas management with radioactive iodine provided 71% benefit. More significant might be the incidence of hypothyroidism in the two series, in which the surgically operated patients developed a 5% incidence of hypothyroidism whereas the radioactive iodine-treated patients developed a 20% incidence.

The authors were able to conclude that under modern conditions sub-total thyroidectomy is still a good and safe form of therapy for hyperthyroidism, resulting in fewer long-term complications than any other method presently available.

FORECASTING THE SEX OF THE UNBORN CHILD

Given a long needle, a bottle of cresyl violet stain, some alcohol, and a microscope, one can predict the sex of a fetus in the uterus with 100 per cent accuracy. Doctors A. P. Amarose, A. J. Wallingford, and E. J. Plotz of the Albany Medical College report that a cytogeneticist* and three technicians correctly forecast the sex of 31 unborn children by studying amniotic fluid from Rh-negative sensitized women. In fetal cells from males, examiners see no sex-chromatin bodies. Twenty to 40 per cent of females have a sex-chromatin mass. Removing fluid from the amniotic sac can be dangerous and should not be used to satisfy the curiosity of expectant patients, but physicians who have reason to diagnose sex-linked hereditary diseases may want to use the technique as a tool in preventative genetics.

DISEASES OF BRAIN AND ABDOMEN AND PH

Before the advent of pH. measurement, most physicians relied on the CO₂ content as an indicator of acid-base imbalance. Dr. Gambino, clinical pathologist at Englewood Hospital in New Jersey, exposes the hazards of this approach. He presents nine patients who had normal carbon dioxide levels but who showed pH.s ranging from 7.51 to 7.59. Each patient had a serious intracerebral or intraabdominal disease. Dr. Gambino calls the combination of an elevated pH. and normal CO₂ "unsuspected venous alkalemia," and says it is frequent in patients with peritonitis, ascites, liver coma, and hypertensive encephalopathy.

Minneapolis, Minnesota

Gambino, R. S.: Unsuspected Venous Alkalemia—A Laboratory Sign of Serious Disease. JAMA 198:484, 1966.

BILATERAL CARCINOMA OF THE BREAST

Bilateral carcinoma of the breast is thought to occur at an incidence rate of about 6.5%. This is not necessarily simultaneous but occurs during the life of the individual. Simultaneous carcinoma occurred in about 1%.

The authors pointed out that some authorities therefore have recommended simple mastectomy on the uninvolved side.

PERNICIOUS ANEMIA IN CHILDHOOD

The prototype for pernicious anemia: a middle-aged or elderly patient with gray hair, blue eyes, lemon skin and neurological difficulty, is so much a part of medical lore that many doctors do not think of the disease in children. Yet two types of pernicious anemia exist in childhood: the adult type with gastric atrophy and the juvenile congenital type with congenital lack of the intrinsic factor and no abnormality of the stomach and its secretions.

Miller and his colleagues from the Harvard Medical School present three male infants who had onset of pernicious anemia at eight months, nine months and seventeen months. All had low levels of serum B₁₂, megaloblastic anemia, and absent intrinsic factor with normal gastric secretion and normal gastric mucosal histology. The intrinsic factor corrected the absorption defect in all children, and the histology remained normal five, eleven and twenty-nine years after intrinsic B₁₂ or liver extract therapy. The investigators studied 43 relatives and found no increased incidence of intrinsic factor or parietal cell antibodies, both common in patients with adult pernicious anemia. Childhood pernicious anemia, they conclude, does not predispose to gastric atrophy.

BLOOD CLOTTING AND THE PILL

Doctors started to prescribe contraceptive drugs to the public in 1960. Although several blue ribbon committees, including one supported by the Federal Drug Administration, declared the drugs safe, the literature abounds with reports of thrombophlebitis and pulmonary emboli; and lingering doubts about the safety of the drug remain. Poller and Thomson of the Eithington Hospital in Manchester, England, studied the effects of oral contraceptives on clotting in a large group of women taking a variety of commercial preparations. Nearly all subjects showed a significant increase in Factor VII Level after they had received drugs for three months. The investigators also detected elevated Factor VII Levels in pregnant patients, post-partum females and individuals with deep thrombosis. Potter and Thomson conclude that the Factor VII increase is an undesirable side effect of oral contraception, and doctors should use drugs discretely for limited time periods.

The best time to loaf is after you're dead.—Forbes Epigrams

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical

facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

Book Reviews

When a book raises your spirit, and inspires you with noble and manly thoughts, seek for no other test of its excellence.—It is good, and made by a good workman.

—Bruyere

THE PEDIATRICIAN'S OPHTHALMOLOGY—Edited by Sumner D. Liebman, M.D., and Sydney S. Gillis, M.D., St. Louis, C. V. Mosby Co., 1966. 337 pages, 120 illustrations, 7 color plates, chapter references, index. Price: \$19.50.

This comprehensive book is, to the reviewer's knowledge, the best available in the interesting area of eye conditions of children, especially as they fit into the various syndromes. It is the result of well edited contributions of 25 authors covering 19 subjects. Both as fascinating reading as well as organized and detailed reference material it should be in the library of the pediatrician and the ophthalmologist. There is a useful table of inherited syndromes as well as a glossary of ophthalmic language. In the section on reading disability, the complexity of diagnostic terms and the brevity of the discussion on treatment underline the real lack of knowledge in this distressing area. From the reviewer's personal experience, this book should be read before taking the American Board of Ophthalmology.

William S. McClanahan, M.D.
Meriden, Connecticut

MENTAL RETARDATION — A Family Study by Elizabeth W. Reed, Ph.D. and Sheldon C. Reed, Ph.D. W. B. Saunders Company, Philadelphia and London, 1965. 716 pp.

Anyone who counsels or treats a mentally subnormal individual needs this book. It is not only an excellent resource for genetic counseling, but also a thorough and objective investigation of mental subnormality. To achieve their goals the authors examined data on the mental status, economic, educational, and social achievements of 82,217 persons. All of these persons were in some way related to 289 patients hospitalized at the Faribault State School for The Retarded between 1911 and 1918. By a careful compilation and evaluation of this material the authors unquestionably prove the following:

(1) The greatest predisposing factor for the appearance of mental retardation is the presence of retardation in one or more relatives.

(2) Cultural deprivation may lower the intellectual performance of any person, but if the polygenetic theory

of intelligence is valid there is little opportunity for cultural deficiencies to be the primary cause of retardation.

(3) When voluntary sterilization for the retarded becomes part of the culture of the United States, we should expect a decrease of about 50% per generation in the number of retarded persons as a result of all methods combined to reduce retardation.

The above conclusions are only a few of the provocative and interesting ones found in this book. Those inclined to emotional thinking will undoubtedly deny many of these conclusions, yet the evidence offered by the authors is compelling. The book is a long one, but the meat of it is in the first 79 pages. The remaining 637 pages consist of an elaborate and detailed appendix including a pedigree of all persons studied. Throughout the book, one is impressed with the crisp literary style and lack of jargon. All told, the book is excellent in every respect, and belongs on many bookshelves.

James Janecek, M.D.
St. Paul, Minnesota

SURGICAL DISEASES OF THE CHEST — Edited by Brian Blades. Second Edition 9/66, \$25.00. C. V. Mosby.

This is a fine text covering a rather extensive field. The major change from the previous edition has been in the sections dealing with cardiac abnormalities and their surgical correction. The rapidly changing field of cardiovascular chest surgery almost precludes any text from being completely current, and this applies to this effort. However, by the same token, current procedures now popular that will soon be phased out of practice are avoided.

The book contains 687 pages with a good bibliography at the end of each chapter section. There are chapters covering basic thoracic physiology and postoperative care of the thoracic surgical patient. Chapters on extra corporeal circulation and hypothermia, anesthesia, and ancillary procedures such as bronchoscopy and esophagoscopy are included.

The surgical trainee should find the book particularly valuable, and to those advanced physicians with a special interest in this field it will provide a good reference source.

Tandearil®

oxyphenbutazone

Tandearil in Painful Shoulder

Therapeutic Effects: Stiffness and pain may diminish within 2 days, and full mobility may be restored within a week. These effects are obtained with oxyphenbutazone alone or combined with physiotherapy or local hormonal injections. The drug is usually well tolerated and does not affect pituitary-adrenal function or immune response.

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should be closely supervised and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage. Make regular blood counts. Discontinue the drug and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, or a generalized allergic reaction may occur and require withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Painful Shoulder: 600 mg. daily in divided doses for 2 to 3 days; 300 mg. daily thereafter. Usual duration of therapy: 2 to 7 days.

Availability: Tablets of 100 mg.

Athletic Injuries

Preseason Conditioning Exercises For High School Football Players^{*}

EDWARD D. HENDERSON, M.D., Chairman
DONALD J. ERICKSON M.D.
Rochester, Minnesota

MANY PHYSICIANS and coaches have long recognized the need for preseason conditioning before participation in competitive sports by both high school and college athletes as one means of reducing the incidence of injuries. The report by Honet and associates¹ showed that various aspects of physical fitness require several months of conditioning exercises for optimal development. Preconditioning was associated with an increase in maximal work output during the first two months of participation in high school football, whereas the control group (nonconditioned) showed a decline in maximal work output: results which indicated a need to reevaluate the effectiveness of the present system of training prior to the commencement of the football season. Other studies² have also shown that various aspects of physical fitness require at least several months of conditioning for optimal development.

Conflicting Rules

The National Federation of State High School Athletic Associations has recommended a period of several months of conditioning exercises prior to the onset of the athletic season.¹ However, this recommendation may be carried out in Minnesota only at the expense of violating the rules of the Minnesota State High School League as published in the official handbook:³

1. Practice may begin two (2) weeks prior to the first Monday in September.

2. Practice and the season will be terminated upon completion of the final game on the Official Schedule for each school.

3. No school may engage in any football game or games, practice, training or other football activities between the close of one season and the opening of the next season. . . . This regulation includes conditioning, training, or instruction conducted directly or indirectly by school officials or other interested individuals with the exception of the secondary students.

4. For practice sessions, the handbook states that two (2) weeks of organized practice ". . . must precede the first game. . . . nine (9) separate and complete days of practice must be held before school engages in interscholastic games." In addition: "Inter-school practice scrimmages may not be held until after five (5) separate and complete days of organized practice."

Therefore supervised or organized conditioning exercises prior to the opening date for practice would be considered a violation of the 1965-1966 rules of the Minnesota State High School League, and in apparent conflict¹ with the recommendations of the National Federation of State High School Associations, of which Minnesota is a member.

Preseason Program of Exercises

Addressing itself to this problem, the Committee on Sports Medicine of the Minnesota State Medical Association has formulated a program of exercises which is available to all high schools throughout the state. Thus, all the participants in competitive sports have an equal opportunity to undertake a program of preseason conditioning that will increase the level of physical fitness prior to the organized football practice in an effort to reduce the in-

^{*}Published under the direction of the Committee on Medical Aspects of Sports of the Minnesota State Medical Association.

Continued

cidence of such injuries as are frequent in the early part of the season. However, it should be emphasized that physical fitness is only one of the factors that reduces the number of football injuries. Other factors are good coaching, proper equipment, adequate officiating, and good condition of the playing field.

A Physical Educator.

A careful search of the medical literature, as well as the literature in the field of physical education, failed to reveal a simplified program of progressive exercises for high school students without the need for uniforms or equipment. In the program of exercises to be presented, it is highly desirable that a trained leader, preferably a physical educator, lead the group on a regular basis so as to give continuity to the program as well as to ensure that the participants gradually increase the intensity of the exercises.

The exercises to be described are designed to improve the cardiovascular function, to strengthen muscles of the trunk and extremities, and to increase the flexibility of the body and legs. It is understood that once organized practice has

begun, the coach will take over the program of exercises as part of the practice training.

Captain's Practice.

These exercises were presented to representatives of the Minnesota State High School League which went on record stating that this program should be strongly encouraged. At the present time students in some high schools do participate in an informal and unsupervised program of preseason exercises known as "captain's practice." These groups of boys meet regularly and perform group exercises under a chosen leader, who may be the team captain.

These exercises should be performed in the order they are presented. The leader should determine the amount of exercise, unless the number is stated with the exercise.

Running

To Develop Endurance and Speed.

1. Begin with a total distance of $\frac{1}{2}$ mile and gradually increase until one mile is run each day. (Suggested routine: first slow, easy *run* for two to three minutes; then sudden, fast *sprint* for 15 to 20 yards; finally a fast *walk* for 50 yards. Repeat the sequence: run, sprint, and walk for the total distance of $\frac{1}{2}$ to one mile. Practice sharp turns to each side while running.) The sprinting may be started quickly on a signal from the leader. The running

Figure 1

Figure 2

should be done up and down hills; some could be done on steps or stairs, as in the stadium.

2. Run backward at best speed for 15 to 20 yards, and then quickly run forward for the same distance. Repeat two or three times.
3. Hop for 25 yards on one foot and repeat with the other foot. Hold opposite knee high, keeping hands on hips. Repeat two or three times.

To Condition Ankles (Figure 1).

Place chalk lines 15 inches on either side of a center line. Run with the feet apart, placing feet on outer lines.

Standing

To Increase Flexibility of the Trunk.

Side Bender (Figure 2).

Cadence: Moderately slow.

Starting position: Stand with feet apart, hands clasped over head and arms straight.

Movement:

1. With the right knee straight, bend body sideward slowly and as far as possible to the right.
2. Return to starting position.
3. Repeat (1) to left.

Repeat 10 times for each side.

Trunk Twister (Figure 3).

Cadence: Moderately slow.

Starting position: Stand with feet apart, hands behind head and knees straight.

Movement:

1. With knees straight, bend body obliquely to left and bring right elbow toward left thigh.
2. Return to starting position.
3. With knees straight, bend body obliquely to right and bring left elbow toward right thigh.
4. Return to starting position.
5. With knees straight, bend forward as far as possible.
6. Return to starting position.
7. With knees straight, bend backward as far as possible.

Repeat each movement 10 times.

Figure 3

To Strengthen Legs and Improve Endurance.

Stationary Run (Figure 4).

Cadence: First slow, then fast, then slow.

Starting position: Stand erect, with arms at thrust and fists lightly clenched.

Movement:

1. Begin slowly and speed up somewhat, raising knees to the height of the hips.
2. Run for a while at full speed, raising knees forcibly, then slow down.

From $\frac{1}{2}$ to one minute should be spent on this exercise.

Figure 4

To Stretch Hamstring Muscles.

Hamstring Stretch (Figure 5).

Cadence: Moderate.

Starting position: Stand erect.

Movement:

Continued

1. Bend forward at the waist, with knees straight, and touch ground between feet.
2. Relax slightly and "bob" downward again, touching ground from 6 to 8 inches farther forward.
3. Repeat (2), touching ground still farther forward.
4. Return to starting position.

To Strengthen Upper Back Muscles and to Stretch Muscles of the Chest.

Shoulder-Blade Squeezer (Figure 6).

Cadence: Slow.

Starting position: Stand erect, with feet together and arms forward and level with shoulders.

Movement:

1. Swing arms sideward and backward as far as possible.
2. Relax slightly and swing arms backward again.
3. Repeat (2).
4. Return to starting position.

To Strengthen Muscles of the Neck.

Neck Firm (Figure 7).

Cadence: Moderate-to-slow.

Starting position: Stand erect, with fingers laced behind head.

Movement: (isometric)

1. Keeping elbows back, raise chest high,

Figure 5

Figure 6

Figure 7

PRESEASON CONDITIONING EXERCISES

pulling head backward against resistance of hands. Repeat five times.

2. With fingers laced and held against forehead, push head forward against resistance. Repeat five times.
3. Hold left hand against left side of head. Attempt to touch ear to left shoulder, resisting motion with left hand. Repeat five times.
4. Reverse (3) to right side. Repeat five times.
5. Rotation. Place right hand on right side of lower jaw. Attempt to turn head to the right against resistance. Repeat five times.
6. Rotation. Reverse of (5). Repeat five times.
7. Circumduction. Tense all muscles of neck and move head in complete range of movement, first in clockwise motion and then counter-clockwise. Repeat five times in each direction.

Sitting

To Strengthen Abdominal Muscles.

Abdominal Strengthening—Sit-up (Figure 8).

Figure 8

Cadence: Moderate.

Starting position: Lie on back, with knees bent and hands behind neck, feet held flat on ground by a teammate.

Movement:

1. Come to sitting position by "curling" the trunk, touching right elbow to left knee.
2. Relax slowly to recumbent position.
3. Repeat, touching right elbow to left knee first and then left elbow to right knee.
4. Come to sitting position, bringing head to between the flexed knees.

Repeat 10 to 30 times.

To Stretch Back and Hamstrings.

Hamstring Stretch (Figure 9).

Cadence: Moderate.

Figure 9

Figure 10

Starting position: Sit with knees straight.

Movement:

1. Bend forward and touch toes or grasp ankles while pulling trunk forward as far as possible.
2. "Bounce" downward three times.
3. Return to starting position.

Repeat five to 10 times.

To Strengthen the Muscles of the Groin.

Groin Strengthening (Figure 10).

Cadence: Moderate.

Starting position: Sit with legs outstretched and hands at side or in back of trunk for support, legs grasped at the ankles and held firmly by a teammate.

Movement: (isometric)

1. Move the legs against resistance of the teammate in strong efforts to bring the feet together.
2. Repeat above, except move legs apart against resistance.

Lying On Back (Supine Position)

To Increase Flexibility of the Trunk and to Strengthen Muscles of the Upper Back.

Leg-Back Stretch (Figure 11).

Cadence: Moderate.

Starting position: Lie flat on back, with arms outstretched at right angles to the trunk and palms flat on ground.

Movement:

With knees stiff and without moving shoulders, raise one leg to perpendicular position and swing it across the body until foot touches opposite hand.

Repeat 10 to 15 times for each leg.

To Strengthen the Muscles of the Legs and Trunk.

Bicycle (Figure 12).

Cadence: Moderate.

Starting position: Support body on shoulders, with elbows on ground and hands on hips.

Movement:

Raise legs and body as high as necessary in order to move feet and legs as rapidly as possible in an alternate motion, as in riding a bicycle.

Repeat 20 to 30 times.

To Strengthen Legs and Abdominal Muscles.

Leg Raiser-Straight Leg Raising (Figure 13).

Cadence: Moderate.

Figure 11

Figure 12

Figure 13

PRESEASON CONDITIONING EXERCISES

Starting position: Lie on back with feet together and arms at side of body.

Movement:

1. Raise left leg upward to the vertical.
2. With knees straight, lower left leg and at the same time raise right leg to the vertical.

Repeat 20 to 30 times.

To Strengthen the Muscles of Neck and Back.

Wrestler's Bridge (Figure 14).

Figure 14

Figure 15

Figure 16

Figure 17

Cadence: Moderate-to-slow.

Starting position: Lie on back, with feet drawn up about a foot below hips, knees bent slightly farther than a right angle, fists clenched and placed by side of head, elbows forward.

Movement:

1. Raise the body as high as possible, resting the weight on fists, head, and feet.
2. Recover to starting position.

Repeat three to five times.

To Strengthen Muscles of the Hips.

Leg-Side Raiser (Figure 15).

Cadence: Moderate.

Starting position: Lie full length on right side, with head resting on outstretched right arm.

Movement:

1. Raise left leg as high as possible, keeping knee straight and leg in line with the body.
2. Repeat on left side, raising right leg as high as possible.

Repeat 20 to 30 times on each side.

Lying On Abdomen (Prone Position)

To Strengthen Muscles of Arms.

Push-up (Figure 16).

Cadence: Moderate.

Starting position: Rest with hands on ground on either side of chest, knees and hips straight.

Movement:

1. Bend elbows and touch chest to ground, keeping body straight.
2. Straighten elbows, raising body to straight line.

Repeat 10 to 20 times.

To Strengthen Muscles of Back and Neck.

Back Strengthening (Figure 17).

Cadence: Moderate.

Starting position: Lie on stomach, with hands behind head.

Movement:

1. With knees straight, arch back, lifting feet, legs, head, and chest off ground.
2. Repeat with arms extended fully over head.

Do each exercise 10 to 20 times.

Continued

To Strengthen the Muscles of the Extremities.

All Fours (Figure 18).

Cadence: Moderate.

Starting position: Lie with weight on hands and feet.

Movement:

Walk forward, backward, and sideward on hands and feet.

Figure 18

To Strengthen the Muscles of the Trunk and Extremities.

Elbow Extension Press-up (Figure 19).

Cadence: Moderate.

Starting position: Lie face down with legs straight out and hands clasped behind head.

Movement:

Resting on toes and elbows, lift all other parts of the body up away from the ground. Hold for count of three.

Repeat three to five times slowly.

Hand Extension Press-up

(alternative to Elbow Extension Press-up).

Cadence: Moderate.

Starting position: Lie face down with legs straight out and arms straight out as far as possible above head.

Movement:

Keeping elbows straight, press up on toes and hands. (This can be made into a competition by seeing how long each in-

Figure 19

Figure 20

Figure 21

PRESEASON CONDITIONING EXERCISES

dividual can hold the position, with waist-line six inches from the ground.)

To Strengthen the Muscles of the Arms and Legs.

One-Hand Spider Drill (Figure 20).

Cadence: Moderate.

Starting position: Sit on right thigh, with legs outstretched, trunk leaning backward and weight resting on right arm.

Movement:

1. Straighten body to side-leaning rest position by raising hips and thighs as high as possible.
2. Walk in side-leaning position in a complete circle with the hand as the center of the circle of movement.

3. Repeat (2) but use opposite hand for support and walk in side-leaning position in opposite direction.

Repeat each exercise several times.

To Condition Chest.

Bouncer (Figure 21).

Cadence: Moderate.

Starting position: Lie flat on abdomen, with hands on ground.

Movement:

Start a push-up; quickly whip arms out to sides while dropping body to ground. Head should be back or turned to either side for the drop.

Repeat 10 to 20 times.

It's the Law

Surgeon Physically Unable To Practice Specialty Is Totally Disabled

An insured physician, whose practice had been exclusively surgical, but who no longer could engage in such practice because of dermatitis on his hands, was entitled to benefits for total disability even though he was employed.

This physician was able to demonstrate to the court that, in the 10 years prior to his disability, his practice had been entirely surgical. Dermatitis developed on his hands, and despite continuous treatment, the dermatitis was not cured and flared up every time he scrubbed for surgery. The physician gave up his surgical practice and took a salaried position in a Veterans Administration Hospital.

The court ruled that, because of his inability to practice surgery, benefits were payable.

INFLAMMATION: A cellular fight for life

A SYNTEX REPORT based on recently developed hypotheses about topical corticosteroids, including the cellular theories of inflammation by Thomas F. Dougherty, Ph.D., University of Utah.

You are looking at a fibroblast fighting for life. This cell—one of the most common found in connective tissue—has literally been poisoned by cytotoxins released from other cells that have ruptured. Soon, if the abnormal activity of this fibroblast does not cease, it, too, will rupture and die—one more casualty in the inflammatory wave of destruction precipitated by injury.

Until a short time ago no one had ever witnessed such a scene at the cellular level. Now, through advanced cinemicrographic techniques, it is possible to view and photograph the inflammatory process as produced experimentally in living animal tissue. This method permits new insight into the mechanism of inflammation and the role of corticosteroids in therapeutic management. Equally important, these techniques shed new light on factors that may make one corticosteroid more effective than another—factors that can be correlated with other chemical, biologic, and clinical parameters.

Visual evidence of how corticosteroids influence the inflammatory reaction

Working with phase-contrast cine-micrography on living animal tissue, Doctors Thomas F. Dougherty and David Berliner of the University of Utah College of Medicine have actually filmed cellular events that occur during the inflammatory reaction. This remarkable study* and additional work by these investigators, as well as by others, have established a new theoretical biologic basis for the antiinflammatory effect of the corticosteroids. (It must be noted that other theories, such as the lysosome or so-called "suicide bag" theory, have been postulated, although it is quite likely that there are more similarities than differences among the various theoretical models.)

The inflammatory wave of destruction

In this investigation an injurious injection of gelatin is used to set off an inflammatory reaction in living mouse tissue. What follows is a wave of destructive cellular activity that comprises the inflammatory response to injury. Mast cells (which contain heparin, serotonin and histamine) take up water, swell and rupture, releasing their contents, which are toxic outside the mast cell wall. These toxins, in turn, cause disintegration of other cells (such as fibroblasts) and the release of additional toxic material. Capillaries, too, take up water and leak unformed blood elements, causing edema. And polymorphonuclears, lymphocytes and perithelial cells invade the inflamed site. As a result of all these changes, the cellular environment reaches a state of turmoil.

Phase-contrast microscopy showing mast cell before injury.

Mast cell (after injury) has broken up and released cytotoxins.

How corticosteroids change the picture

Corticosteroids appear to virtually stop the abnormal cellular activity that constitutes the inflammatory reaction. This permits the body's natural resources to clear up the inflamed area and repair the damaged tissue. This interpretation is supported by the fact that when the injurious gelatin solution is injected simultaneously with a corticosteroid — Synalar (fluocinolone acetonide) — the inflammatory pattern simply does not develop.

Fibroblast in high state of activity, much distorted.

Mast cells showing effects of corticosteroid action; cells are normal in size, shape and activity.

In summarizing his study Doctor Dougherty states: "...we also feel this work may explain why one corticosteroid helps a patient more rapidly and effectively than another. If it does, it is because one corticosteroid is the fastest, most effective inhibitor of the series of inflammatory events at the tissue level."

*A New View of Corticosteroid Action in Inflammatory Dermatoses, a film based on this study, is now available from your Syntex representative.

How advances in chemical design have achieved greater steroid potency

The chemical modification of corticosteroid molecules from the advent of hydrocortisone to the development of Synalar (fluocinolone acetonide) is a prime example of how biochemists can "design" to increase therapeutic activity and minimize undesirable side actions. Below, for example, we see the important changes that were made in reference to the hydrocortisone molecule to produce fluocinolone acetonide, one of the most active of all topical corticosteroids. As a result, a 0.01% preparation of Synalar (fluocinolone acetonide) has been reported to do the work of a 1% hydrocortisone product containing 100 times more corticosteroid. And it can often do it more effectively.

Hydrocortisone

Fluocinolone Acetonide (Synalar)

- ☐ a double bond between carbons 1 and 2
- ☐ fluorine substitutions at both the 6- α , and the 9- α positions
- ☐ the addition of the acetonide at the 16- α , 17- α positions, thus providing one of the most potent topical corticosteroids available.

How bioassay tests are used to "predict" therapeutic potential

Biologic assays are another tool used by researchers to help establish the relative activity of corticosteroids. To date no single method of assaying corticosteroid activity has emerged as the ideal "yardstick" for predicting therapeutic potential. Taken together, however, these methods have proved useful. When such tests are run on various corticosteroids, a definite order of corticosteroid activity becomes evident. Compounds with the highest order of activity may be expected to merit clinical trial to establish their high therapeutic potential. When assayed by these methods, fluocinolone acetonide (Synalar) emerges as one of the most active topical corticosteroids, milligram for milligram, available for clinical application today.

THE THYMUS INVOLUTION ASSAY¹⁻⁴ is run on adrenalectomized rats. The sizes of the glands are measured, and the degree of involution caused by the steroid is determined as an indication of its potency. In the above photo, the comparative involution of thymus glands achieved with hydrocortisone and Synalar (fluocinolone acetonide) is shown. Untreated controls (A) show normal size. Group B— injected with 1, 2 and 4 mg. of hydrocortisone—show progressively smaller thymuses as does Group C— injected with fluocinolone acetonide—but with only 1/500th the dose of hydrocortisone.

THE ANTIGRANULOMA ASSAY¹⁻⁴ also utilizes adrenalectomized rats. Granulomas are induced by subcutaneous implantation of cotton pellets on either side of the thorax. The degree of granuloma inhibition achieved by a steroid reflects its potency. The above photo shows the inhibition of granuloma formation achieved with hydrocortisone and Synalar (fluocinolone acetonide). Untreated controls (A) show large, red granulomas adhering to the pellets. Group B, receiving hydrocortisone and Group C, receiving fluocinolone acetonide, show little, if any, granuloma formation. Fluocinolone acetonide produced the same effect as hydrocortisone with only 1/500th the dose. This assay, as well as the thymus involution assay, measures systemic rather than topical corticosteroid activity. Nevertheless, results by these methods correlate well with other assays and with the milligram potencies of topical steroids in current clinical use.

Worldwide clinical experience confirms the predictable therapeutic potential of Synalar

It is particularly gratifying that the promise of the advanced chemical design and high order of bioassay activity of Synalar (fluocinolone acetate) has been confirmed by widespread therapeutic application. Indeed, the impressive clinical response rate of Synalar has been documented in no fewer than 232 papers from 22 countries.

PRESCRIBING INFORMATION

For initiation of therapy: Cream 0.025%, 5 and 15 Gm. tubes, 425 Gm. jars; *for emollient effect:* Ointment 0.025%, 15 Gm. tubes; *for maintenance therapy:* Cream 0.01%, 15 and 45 Gm. tubes, 120 Gm. jars; *for intertriginous or hairy sites:* Solution 0.01%, 20 cc. and 60 cc. plastic squeeze bottles; *for infected inflammatory dermatoses:* Neo-Synalar® Cream (0.025% fluocinolone acetate, neomycin sulfate, equivalent to 0.35% neomycin base), 5 and 15 Gm. tubes.

CONTRAINDICATIONS: Tuberculous, fungal, and most viral lesions of the skin, (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. **Contraindicated** in individuals with a history of hypersensitivity to any of the components. **PRECAUTIONS:** Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for pro-

longed periods of time. Prolonged use of any antibiotic may result in overgrowth of nonsusceptible organisms; if this occurs, appropriate therapy should be instituted. When severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. **SIDE EFFECTS:** Side effects are not ordinarily encountered with topically applied corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. The neomycin in Neo-Synalar Cream rarely produces allergic reactions.

Anxiety and tension stemming from organic illness may undermine your patient's cooperation and possibly retard success of primary therapy.

If his emotional symptoms persist in the face of your counsel and reassurance, you may want to consider adjunctive use of SERAX (oxazepam). It is indicated in anxiety, tension, agitation, irritability, and anxiety associated with depression. May be used in a broad range of patients, usually with considerable dosage flexibility.

When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly and when complications could ensue from a fall in blood pressure. (See Wyeth literature or PDR as well as "IN BRIEF" below.)

IN BRIEF.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures.

Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance. Safety for use in pregnancy has not been established.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Side Effects: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leucopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam.

To help you relieve anxiety and tension

Doctors **Cameron G. Strong**, **Wiley M. Sams, Jr.**, **William P. Wharton**, **Carl Bernofsky**, **James Trautmann**, **Gerald A. Gronert**, **William W. Douglas** and **Jurgen Ludwig** have been appointed to the staff of the Mayo Clinic, Rochester.

* * *

Dr. Clarence J. Rowe, St. Paul, has been reappointed a member of the Committee on Mental Health in Industry of the American Medical Association.

* * *

J. C. Whitacre, II, M.D., has returned to Minneapolis after an absence of almost five years and opened an office for the practice of psychiatry in Minneapolis. During this period Dr. Whitacre studied in New York, Oklahoma and St. Louis completing his formal residency training at The Jewish Hospital of St. Louis, June 30 1967.

* * *

Newly elected members of the Minnesota Heart Association are: **Dr. John J. Juergens** of the Mayo Clinic, president; **Dr. James H. Kelly**, St. Cloud, president-elect; **E. William Quirin**, Rochester, second vice-president; **Dr. John Fee**, St. Paul, secretary; and **John L. Olson**, St. Paul, treasurer.

* * *

Doctors **Norman Goldstein**, **Alfred Uihlein** and **James Kernohan** of the Mayo Clinic were among the participants at the 21st National Convention of the American Trial Lawyers in Minneapolis during July.

Special Article

A Volunteer Physician in Vietnam

AFTER RECEIVING the assignment for Sixty Days in one of the provincial hospitals in Rach Gia, we were furnished with a round-trip, tourist-class airline ticket to Saigon. We were reimbursed at the rate of \$10.00 per day, a sum which adequately covered our living expenses.

The hospital was an old, one-story structure, built by the French with shutters to keep out the rain. The operating theater had been modernized by our government, and of the 350 beds, 100 were designated for use by our surgical unit.

Most of our work consisted of taking care of war casualties among the civilians and Vietnamese soldiers, though we also attended many Viet Cong members.

Cancer of the breast was usually far advanced; appendicitis was often found to be due to a ruptured appendix; and maternity problems were complicated because all normal deliveries were attended by midwives. Malaria was infrequent but parasitic disease was common, the *Ascaris* (roundworm) being often found within the peritoneal cavity when operating for bullet wounds.

We were pleasantly surprised at the recuperative powers of the Vietnamese people and their good response to antibiotics. Even though we often used large doses of chloromycetin, we observed no case of agranulocytosis or marrow depletion.

Most severe burns were caused by carelessness and the disregard for gasoline which the natives seemed to regard as similar to kerosene.

The city of Rach Gia has a population of 40,000 inhabitants. Curfew is at 9 P.M. when everybody gets off the streets, roads and rivers. After curfew the

Continued

saying goes: "The roads belong to the Viet Cong." Our little house, which for the sake of morale was called "Rach Gia-Hilton", is located on the river and adjacent to the hospital. Fishing boats line the river and in the background is the Gulf of Siam.

Here Dr. Pearson is treating a patient with Buerger's disease who has lost one foot and one hand but still refuses to give up his favorite brand of cigarettes which he pronounces "Saléme."

These four young women are midwives in the hospital. Watching them deliver babies, we found them to be very capable. All of them wish they could obtain a scholarship to America.

PHYSICIAN IN VIETNAM

The space between "Surgery" and "Emergency" is always filled with relatives and curious onlookers. The two girls in the foreground are native nurses.

Giving a prescription to natives is often done during the "Siesta" hour. These prescriptions can be filled at the hospital pharmacy or the Chinese pharmacy downtown. Workers insist on being paid not only for their own special holidays, but even for American holidays. Eighty per cent of the people are Buddhists.

Our house situated on the beach of Rach Gia River. Our group of doctors employed a cook and two servants.

Continued

Siesta hour is between 12:00 and 2:30, when everything stops, including the electricity, shutting off fans and refrigerators, and a large padlock must be placed on the Emergency Room so that if anyone arrives during the interval, it is "Syn Loi" (too bad). Here four American doctors are having their Siesta on the front lawn of their small house, on the banks of the river. In Vietnam rain comes twice daily and there is no shortage of water.

The birthrate is high and the infant mortality surprisingly low. Children appear well nourished; they live mostly on rice and fish.

Writing to my wife was usually done during the Siesta hour. In the background our private guard walks the river. There is no place in Vietnam which is one hundred percent secure; though Rach-Gia was considered to be only thirty-five percent secure, I felt in no danger. No American physician serving as a volunteer to these civilians has ever been harmed. I returned home with an increased respect and pride for our men in uniform and for the dedicated people who serve with the United States Agency for International Development. They live and work under frustrating and difficult conditions. Above all, I returned from this assignment with an increased appreciation of the amenities and advantages Americans enjoy and the privilege of being able

to come home to a great country like ours. I gained the impression that the majority of Vietnamese people, both North and South, would be eager to settle their differences on their own democratic terms, safely outside the dimensions of communist ideology. I found them all to be gracious, peace-loving citizens.

Bror Pearson, M.D.*
Shakopee, Minnesota

Remedies Derived From the Camel

A camel's brains, dried and taken in vinegar, are a cure, they say, for epilepsy: the same, too, with the gall, taken with honey; which is a remedy also for quinzey. A camel's tail dried, it is said, is productive of diarrhoea, and ashes of burnt camel's dung, mixed with oil, make the hair curl. These ashes, applied topically, are very useful for dysentery, as also taken in drink, the proper dose being a pinch in three fingers at a time; they are curative also of epilepsy. Camel's urine, it is said, is good for the cure of running sores.—Pliny

Law and Medicine

Therapeutic Abortion at the Mayo Clinic*

1945-1965

ALTHOUGH ETHICAL physicians find the act of abortion distasteful, occasionally circumstances exist in which the distaste for this procedure must yield to conscientious reason.

The legal profession has been attempting to clarify the authorization for abortion within certain limits. At present there is little variation in the laws regulating abortion in each state, and the fundamental principle of these laws is to preserve the life of the mother as well as that of her unborn child.¹⁰ In his interpretation of the law each physician is governed by his (1) medical knowledge, (2) medical ethics, (3) religion, and (4) degree of emotional involvement with his patient. However, the goal of both the legal and medical professions is to protect the well-being of the patient and, if possible, that of her offspring with the least possible risk.

Recently it has become evident that certain groups in the medical profession are seeking to liberalize the law as it pertains to therapeutic abortion. Legislation has been sought to approve abortion when (1) the physical or mental health of the mother is in danger, (2) the physical or mental health of the child is in danger, (3) the pregnancy has resulted from rape or incest, or (4) the pregnant patient is less than an arbitrary age, usually 15 or 16 years.

The desire to liberalize the law in this manner is thought-provoking, especially to obstetricians.

Pregnancies resulting from rape and incest and pregnancies in young girls can become medical or psychiatric problems. Frequently, however, the cause of these pregnancies is a social problem, not a medical one.

The present study is an appraisal of the indications for therapeutic abortion at the Mayo Clinic from 1945 to 1965. The purpose was to determine whether there have been changes in the medical or social indications for therapeutic abortion at this institution. A study was published in 1957 for the period from 1945 to 1955, and some data from that study have been incorporated in this paper.¹¹

Analysis of Cases

There has been a general decrease in the number of therapeutic abortions done during the second decade in comparison to the first decade (Table 1). The individual disease processes that necessitated therapeutic abortion fall into four major categories: (1) malignancy, (2) renal disease, (3) cardiovascular disease, and (4) neurologic disease—comprising 77% of the abortions done during the period of this study. Twenty-two per cent of the abortions were done for other medical reasons, and one abortion was done for socioeconomic reasons.

Although, in the strictest sense, destruction of a pregnancy during the treatment of carcinoma of the cervix cannot be considered a therapeutic abortion, this indication is included in the tabulation (Table 2). The largest number of abortions

Continued

*Read at the District VI meeting of the American College of Obstetricians and Gynecologists, Omaha, Nebraska, September 29 to October 1, 1966.

done were in patients who had carcinoma of the breast; eight of these 13 patients had metastatic disease.

Three of the five patients with brain tumors had malignancies that were incompletely removed. The remaining two patients were only suspected of having brain tumors. All five patients suffered from convulsive disorders.

Renal tuberculosis	2	0
Total	19	7

The need for radical surgery in the patient with chondrosarcoma of the right hip and the need for radiation therapy in the patients with lymphomas were the indications for abortion in the remaining five patients in this category.

In the group with renal disease, toxemia of pregnancy was the most common indication for therapeutic abortion (Table 3). This decreasing trend probably represents improved control, earlier treatment, and a better understanding of this disease.

The patients with congenital and rheumatic heart disease (Table 4) each had extremely low cardiac reserve. All four patients who underwent abortion because of chronic hypertension had severe retinal changes. The possibility of superimposed toxemia was the indication for interruption of pregnancy. The patient with pulmonary hypertension had suffered pulmonary embolism with infarction. Severe hypertension with low cardiac reserve was the indication for abortion in the patient with periarteritis nodosa.

The indications for abortion because of neurologic disease other than malignancy are listed in Table 5. Four of these abortions were carried out because of an exacerbation of multiple sclerosis or because the disease was far advanced. The patient with myasthenia gravis was a respiratory cripple who had undergone tracheotomy, and the woman with bilateral retinal detachment was considered to have retinal deterioration during the pregnancy. Each of the other patients listed had either progressive complications from her condition or marked residual handicaps.

Other conditions that required therapeutic abortions were numerous (Table 6). One patient with chronic ulcerative colitis had an acute exacerbation of the disease during the pregnancy, and another had secondary hepatic complications. The patient with duodenal ulcer had refractory symptoms complicated by hyperemesis.

All four patients with diabetes mellitus had retinal and renal complications.

One of the psychiatric indications for abortion was schizophrenia, and two abortions were done because of previous severe postpartum depression.

The patient with Raynaud's disease had suffered a sympathetic reflex dystrophy of the lower extremities after a previous pregnancy. The patient with Schoenlein-Henoch purpura had sec-

THERAPEUTIC ABORTION

ondary renal complications. The patient with osteomyelitis was to be in a spica cast for several months, and there was danger of postpartum infection. The patient with rheumatoid arthritis was severely deformed and had had previous exacerbations of her disease after each pregnancy.

Prior to 1949, four pregnancies were aborted because of pulmonary tuberculosis. No pregnancy has been terminated since that time because of this disease.

One patient underwent an abortion for socioeconomic reasons.

Three women had abortions because of fetal indications. Two women had had three stillbirths from erythroblastosis fetalis, and one had had rubella at three- to four-weeks' gestation.

One mother had an abortion because of the possibility of having a second child with fibrocystic disease.

Discussion

The number of patients and the variety of indications for therapeutic abortion make a comprehensive analysis of each indication impossible. Many of these patients had diseases that made continuation of pregnancy untenable. By the same token, a few of the indications for abortion were somewhat tenuous and certainly must be considered as being relative ones.

Medical research and increased therapeutic skill have changed the prognosis of many diseases. Consequently, pulmonary tuberculosis, toxemia of pregnancy, hyperemesis gravidarum, hypertension, infectious nephropathy, thyrotoxicosis, diabetes mellitus, and rheumatic fever only rarely dictate the need for abortion at the present time.^{3,6,9}

Malignancy

When viewing the broad category of malignancy as an indication for abortion, the physician must first consider the disease and then the pregnancy. If the pregnancy restricts tumor treatment, influences tumor growth, or is responsible for progressive complications, abortion may be indicated.^{6,11} Frequently, pregnancy causes increased edema and vascularity of brain tumors, with a worsening of seizure activity. Some breast malignancies appear to be estrogen dependent,

and occasionally the mother may gain some months of life by termination of the pregnancy. Also, some women with rapidly progressive inflammatory breast carcinoma probably should not become pregnant.

Total	10	13

Continued

When a patient can be expected to live with the malignancy to the completion of pregnancy or when the pregnancy does not interfere with treatment, there seems to be little indication for interruption of that pregnancy. Such is the case with carcinoma of the vulva, carcinoma in situ of the cervix, and carcinoma of the colon.

Renal Disease

Chronic renal insufficiency, whatever the cause, may be an indication for therapeutic abortion. If renal failure ensues, the use of the artificial kidney or the consideration for renal transplant should not be hampered by the possibility of superimposed toxemia or obstructive processes caused by an enlarging uterus. Rarely, a similar situation can occur in patients with renal lithiasis or resistant infection of the urinary tract, especially in a patient with a solitary kidney.^{8,9,11}

Cardiovascular Disease

The increasing scope of cardiac surgery has completely altered the indications for therapeutic abortion in congenital and acquired heart disease.^{8,9,11} Few cardiac surgeons hesitate to operate on the pregnant patient at the present time, except in cases requiring prolonged and intensive anticoagulant therapy such as artificial valve implantation. Surgical procedures for coarctation and replacement of aneurysmal dilations are not contraindications to pregnancy. Cerebral aneurysms may rupture and cause acute episodes. These conditions are not necessarily improved by abortion of a pregnancy. With present modes of therapy, hypertension is only rarely uncontrollable.⁶

Fetal Indications

There are few absolute fetal indications for therapeutic abortion. Reports on the incidence

*Mayo Clinic and Mayo Foundation: Section of Obstetrics and Gynecology.

of congenital anomalies after rubella or other viral infections in the first weeks of pregnancy are inconsistent.^{7,12} At present, wholesale therapeutic abortion for these conditions does not seem valid.

The prognosis in erythroblastosis fetalis has been altered by exchange transfusion and recently by intrauterine transfusion. Immunologic studies may further decrease the necessity of therapeutic abortion for this condition.

Comment

Our list of indications for therapeutic abortion is not intended to be all-inclusive, and is meant only to emphasize that the indications are relative. Each complicated pregnancy must be evaluated for therapeutic abortion on its own merits. Abortion is not an innocuous procedure, and, under the best controlled conditions, complications and even death can occur.^{1,2,4,8} Psychic trauma and prolonged guilt reactions in the patient are not the least of these complications.^{4,8} Likewise, compounding the risk is not justifiable. Where therapeutic abortion is performed because of a chronic medical condition, sterilization should be done at the same time.^{5,8}

Conclusions

Clarification of the legal interpretation for therapeutic abortion is different from broadening the base for therapeutic abortion. This analysis of the 100 therapeutic abortions indicates that medical progress has markedly altered some of the indications for therapeutic abortions. However, it does not show that there has been a change in the attitude at this institution toward the relative indications for therapeutic abortion.

ALFRED T. KAPSNER, M.D.

Dr. Alfred T. Kapsner, 54, Princeton physician, died June 2. Born in Pierz, Dr. Kapsner graduated from the University of Minnesota Medical School, and had practiced medicine in Princeton since 1946.

He was a member of the East Central Medical Society, the American Medical Association, the Minnesota State Medical Association, and active in community activities.

Dr. Kapsner is survived by his wife, four sons and one daughter.

GEORGE R. McNEAR, JR., M.D.

Dr. George McNear, Jr., 44, Heron Lake physician, died May 27 at his home. Born in Boston, Massachusetts, Dr. McNear received his Doctor of Medicine degree at the Cornell University Medical School.

He was a member of the Windom Masonic Lodge, Prudence No. 97, A.F.&A.M., American Legion Post 224, the American Medical Association, the Academy of General Practice, the American College of Obstetricians and Gynecologists, the Minnesota State Medical Association and the Southwestern Minnesota Medical Society. He was an honorary Fellow of the Royal Society of Medicine, London, and the Royal College of Obstetrics and Gynecologists.

He is survived by his wife and two sons.

Disease as Reprisal I

*What sin did Miriam commit that she should be smitten with leprosy?
She had incensed the Lord by presuming to criticize Moses for having married
an Ethiopian woman and for being one of God's favorites.*

*And the Lord came down in the pillar of the cloud, and stood in the door of the
tabernacle, and called Aaron and Miriam: and they both came forth.*

*And the cloud departed from off the tabernacle; and, behold, Miriam became
leprous, white as snow: and Aaron looked upon Miriam, and, behold, she was
leprous. (Numbers 12: 5, 10.)*

"You're up ten pounds since your last physical. We're going to have to do something about that."

Get them while they're easily reversible.

Obesity doesn't happen suddenly. This insidious process has its beginning—and the chances of reversing it are better—during the *first 10 to 15 pounds of weight gain*.

When a new dietary pattern must be established, consider the adjunctive use of **BAMADEX SEQUELS**. Combining the proven *anorexigenic* action of d-amphetamine with the *tranquilizing* effect of meprobamate, **BAMADEX SEQUELS** controls appetite throughout the day, usually with a single capsule daily.

Contraindications: Dextro-amphetamine sulfate: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.

Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients

with suicidal tendencies.

Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness. Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Bamadex[®] Sequels[®]

Dextro-amphetamine sulfate (15 mg.)
with Meprobamate (300 mg.)

special formula for a special problem

*specifically formulated
for symptomatic
relief of sinus headache*

Sinus headache is not a single entity,
but a chain reaction of pain.
It is facial pain—deep, dull, aching and
nonpulsating. It is referred pain—
originating in the nose and sinuses but
felt at another site. It may become
generalized pain and tension in head and
neck. It is one or all of these.

The Sinutab formula is designed
for symptomatic relief of sinus headache.

It provides two analgesics to relieve
pain and discomfort...an effective oral
decongestant to reduce mucosal congestion...
and an antihistamine to help
control allergic manifestations.

Side Effects: Epigastric distress, drowsi-
ness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive
or operate machinery if drowsiness occurs.

Use with caution in patients with thyroid
disease, heart disease, hypertension, diabetes
or kidney disease. Excessive dosage or
prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

Public Health Nursing

Guide for Agencies in Developing Written Medical Policies for Public Health Nursing Services*

MEDICAL AND nursing policies serve as a guide for general nursing practice and are essential for the assurance of quality services to patients. Medical policies also promote good professional relationships between the practicing physicians and the (name of agency) nursing staff.

This guide for medical policies has been jointly agreed upon by the Public Health Nursing Committee of the Minnesota State Medical Association and the Section of Nursing, Minnesota Department of Health. The guide is intended to be useful to local public health nursing committees, nurses and physicians in developing their own medical policies. Such policies should apply to local situations and should have the official approval of the Agency's Medical Advisory Committee.

A public health nursing program for any community includes:

1. Part-time or intermittent home nursing care for the physically or mentally ill and disabled.
2. Health counseling.
3. Participation in community measures to prevent disease and to establish needed health services.

In addition to home nursing care services, the public health nurse offers health guidance to the entire family. She serves families through the home, school, at work and in clinics. She has contacts with many persons who are not ill but who might benefit by health instruction and health guidance.

When a community provides public health nursing services, they are available to everyone, rich or poor, and without regard to race, color or creed.

Medical Advisory Committee

It is essential to establish a medical advisory committee to consider and recommend medical policies and standing orders necessary in a pro-

gram of nursing care of the sick at home. In the appointment of such a committee, general practitioners and medical specialists should be considered. Three to five physicians—one of whom should be the physician on the administrative body (County Nursing Committee)—usually compose this group.

Functions of the Medical Advisory Committee

1. Recommend and approve policies regarding the medical aspects of the agency program.
2. Assist in interpretation of the nursing care services to other physicians and persons in the community.
3. Approve any publicity that involves medical information to be sent to physicians or used through public media.
4. Approve the content and frequency of health examinations for the employees of the public health nursing agency before and during employment and to advise regarding a health program for the staff.

The following suggested medical policies may be established by the agency with the approval of the Medical Advisory Committee.

Policies Related to Medical Supervision

Except under highly unusual circumstances, public health nurses are not expected to answer to the direction of persons other than licensed physicians and surgeons. They may, however, carry out nursing procedures under the orders of other licensed health practitioners when such orders are within the limits of the practitioner's licensure and compatible with the role of the public health nurse.

The patient's physician should be contacted when the care is requested by the patient, his family, or others.

Out-of-Town Physicians: If a patient, visiting temporarily in the community, requests treatment

Continued

*Revision of "Guide" published Minnesota Med. February, 1962.

ordered by his home physician, from whom he has written orders, the nurse may give treatment. If the patient remains in the community, the renewal of treatment orders should be secured in accordance with policies established herein.

For physically ill or disabled patients without medical supervision, usually only one visit is made before medical care is arranged. Standing orders approved by the medical advisory committee are to be followed on this visit. Medical supervision is to be advised and available resources for medical care explained. If a *second* or *third* visit is necessary to arrange for medical care, the essential nursing care is to be given but the importance of calling a physician should be re-emphasized. If needed, help is given in obtaining these services. Persons unable to pay for private medical care are to be referred by the nurses to the responsible community agency.

Selection of Physician—If a patient is not under medical care and wishes recommendations concerning securing a private physician, the nurse may advise the family to call the local medical society, the hospital or in a small community the nurse, who may give the family the names of the physicians. The family should then make its own selection.

In an emergency where the family or the family physician cannot be reached, public health nurses should call the medical representative on the nursing committee, a member of the medical advisory committee or the health officer.

Policies Related to Orders for Care

Telephone orders from the patient's physician may be accepted by a professional nurse member of the staff; however, these orders should be confirmed in writing within 48 hours.

Medical orders should be reconfirmed in writing at appropriate intervals and at least every two months. Special attention should be given to renewal of orders to administer hypodermics containing narcotics.

For continued nursing care in long term illness, the patient should be seen by the physician at least every six months.

Orders for medication must include the following information: diagnosis, name of drug, exact dosage of drug, and frequency, method, and site of administration.

Nurses are permitted to give intradermal and

subcutaneous and intramuscular injections on written orders from a physician. The nurse may *not* give intravenous injections, sera or drugs which commonly cause severe reactions. The physician on the nursing committee or a member of the medical advisory committee will be consulted about requests for injections of any questionable drugs.

With the written consent of the physician, a responsible family member or other person approved by the family may be taught to give a subcutaneous and intramuscular injection. (See Policies for Home Health Aide Services.*) Some agencies may wish to develop other policies such as catheterization of male patients.

Policies on Administration of Drugs

In the interest of patient safety, policies governing the administration of certain drugs by the public health nurse should be established.

The nurse should never administer a drug unless she knows the name of the drug and is familiar with its action. A medication bearing a prescription number only must be identified before it is administered. It is important for the nurse to be familiar with the medication she is administering and the reactions of the medication for the purpose of observing the patient intelligently.

Detailed policies for other medications may be desirable.

Guidelines for a Penicillin Policy follow:

Because of the serious problem of reaction to penicillin, the following precautions have been established for the safety of the patients and the protection of the nurses:

1. New patients should be questioned about any type of allergy in themselves or in their family. When assigned to a patient requiring penicillin, the nurse will carry an emergency adrenalin kit whenever she administers medication.

2. The first injection of each series of penicillin is to be administered by the physician. A series is defined as a regular sequence of doses continued for a definite period of time.

3. Further injections may be administered by the nurse on written order of the physician. Before giving each injection, the nurse is to question the patient for symptoms of allergic reaction.

4. It is recommended that the nurse organize her visit so that she will be in the home for 20-30 minutes after she has given the injection, because

*See Minnesota Med 45: 203, 1962.

a reaction may occur after any injection of penicillin.

5. Anaphylactic reaction may occur within 30 seconds after injection, beginning with itching of the eyes, feeling of fullness in the face, tingling of the extremities, tightness of the chest, and choking sensation, pallor, dyspnea, cyanosis, rapid development of shock and death. Nausea, vomiting, and diarrhea may also be present.

6. If anaphylactic reaction occurs in adults, give 0.5 cc. of adrenalin chloride, 1:1000 intramuscularly. WASTE NO TIME. Massage area for quick absorption. If symptoms are not relieved, a repeat dose of 0.5 cc. may be given in ten minutes. Have someone in the home notify the physician immediately while nurse is giving the adrenalin. If alone with the patient, give adrenalin first and then contact physician. Give external treatment for shock. Report the situation to the physician on the nursing committee as soon as convenient.

7. Dosage of adrenalin for children must be made on an individual basis. However, the following scale may be used as a safe guide:

Children under 5 years	0.1 cc
Children between 5-10 years	0.2 cc
Children over 10 years	0.2 cc-0.5 cc
increase proportionately	
according to weight—up to 0.5 cc	

If symptoms are not relieved, repeat only once in ten minutes.

8. Also report to the doctor all other milder reactions observed following a penicillin injection.

Suggested Standing Orders for Nursing Care

The purpose of standing orders is to provide directions for emergency nursing care until the patient's physician can be contacted. Standing orders are endorsed by the medical advisory committee.

Patient with Fever

Take and record TPR. Advise calling physician. Isolate, if communicable disease is suspected. Give sponge bath, if rectal temperature is 102.6° or higher. If abdominal pain is present, advise nothing by mouth until physician's orders are obtained. If there is no abdominal pain, fluids by mouth may be recommended. Boiled water should be given infants.

Conditions of the Eyes

Infants with discharging eyes:

Report immediately to the patient's physician.

Adults:

Foreign bodies in the eye—do not attempt to remove an embedded body. If foreign body is not embedded, carefully remove it with moistened cotton-tipped applicator. If it does not come out after two or three attempts, bandage eye securely but not tightly and refer to physician.

Other Eye Conditions:

Persons with inflamed or discharging eyes should be referred for immediate medical care. In all cases of discharging eyes, stress isolation of the patient.

Conditions of the Ears

Discharging ears:

Cleanse outer ear with cooled, boiled water and cotton. Dry thoroughly. Do not irrigate. Allow free drainage (do not use cotton ear-plugs). Apply lubricant to skin of ear to protect from discharge. Refer to physician.

Foreign body in ears:

Instill warm water if insect is suspected. Obtain medical care immediately. Artificial light may attract an insect.

Infant Diarrhea

Obtain immediate medical care. Stop all food and advise giving only boiled water. Keep buttocks and genitalia clean and dry. Urge careful hand washing by those giving infant care.

Upper Respiratory Infections Including Sore Throat and Earache

Advise medical care. Stress isolation and rest in bed. Take TPR. Encourage fluids and diet as tolerated. Instruct family to burn oral and nasal discharges.

Burns

Mild (skin unbroken, no blisters):

Hold burned part under cold running water for two or three minutes or apply ice.

Severe (all burns other than mild):

Obtain immediate medical care or send patient to hospital at once. Treat the patient for shock. Have him lie down with his head slight-

Continued

ly lowered. Cover him to avoid exposure.

Do not apply ointment.

Chemical:

1. Wash with large quantities of running water (except those caused by phosphorus).

2. Immediately after, cover with loosely applied clean cloth.

3. Avoid use of ointments, greases, powders, and other drugs in first-aid treatment of burns.

4. Treat shock by keeping patient flat, keeping him warm, and reassuring him until arrival of physician.

Dressings

Minor wounds:

Cleanse with soap and water; protect with clean, dry dressing; advise calling physician if indicated.

Major wounds:

Cover with sterile gauze and control bleeding by applying pressure dressings at site of injury. Obtain medical help immediately.

Surgical wounds:

If drainage or bleeding is excessive, call physician immediately. Reinforce dressing if necessary.

Convulsions

Infant and early childhood:

Protect from external injury such as falls and burns. Protect from biting tongue or allowing it to obstruct air passage. This can be done by putting a thick wad of cloth between the teeth, if possible. Keep air passage free from mucus and turn face to one side to prevent aspirating of saliva or vomitus. Obtain medical care. After convulsion subsides and if accompanied by high fever, give tepid water sponge bath continuously until fever is reduced.

Adult:

Protect from external injury and biting of tongue the same as with infants and children. Do not restrain patient. After attack is over, allow patient to sleep without disturbing or questioning him. Obtain medical care.

Poisons

Call a physician *immediately*. He may wish to make use of a regional Poison Information Center. Speed is essential to stop absorption of a poison. If possible, one person should begin first-aid while another calls a physician. The

nature of the poison will determine the first-aid measure to use. Save and give to the physician or hospital the poison container with its intact label and any remaining contents. If the poison is unknown, bring along the vomitus for examination. Do not induce vomiting if:

Patient is in a coma or unconscious

Patient is in convulsions

Patient has swallowed a petroleum product, e.g., kerosene, gasoline, lighter fluid

Patient has swallowed a corrosive poison (symptoms—severe pain, burning sensation in mouth and throat, vomiting)

Swallowed Poisons

Call a physician immediately if the patient has ingested a corrosive poison as:

1. Acid and acid-like corrosives; sodium acid sulfate (toilet bowl cleaners), acetic acid (glacial), sulfuric acid, nitric acid, oxalic acid, hydrofluoric acid (rust removers), iodine, silver nitrate (styptic pencil).

2. Alkali corrosives; sodium hydroxide—lye (drain cleaners), sodium carbonate (washing soda), ammonia water, sodium hypochlorite (household bleach); and

If the patient can swallow, give the following:

For acids: milk, water, or milk of magnesia (1 tablespoon to 1 cup of water)

For alkalis: milk, water, any fruit juice or vinegar

For patients 1-5 years old—1 to 2 cups

For patients 5 years and older—up to 1 quart
If patient has ingested a non-corrosive substance:

Give milk or water and induce vomiting by placing the blunt end of a spoon or your finger at the back of the patient's throat, or by use of this emetic—2 tablespoons of salt in a glass of warm water. When retching and vomiting begin, place patient face down with head lower than hips. This prevents vomitus from entering the lungs and causing further damage.

Inhaled Poisons

1. Carry patient (do not let him walk) to fresh air immediately.

2. Open all doors and windows.

3. Loosen all tight clothing.

4. Apply artificial respiration if breathing has stopped or is irregular.

Continued

5. Prevent chilling (wrap patient in blankets).
6. Keep patient as quiet as possible.
7. If patient is convulsing, keep him in bed in a semidark room; avoid jarring or noise.
8. Do not give alcohol in any form.

Skin Contamination

1. Drench skin with water (shower, hose, faucet).
2. Apply stream of water on skin while removing clothing.
3. Cleanse skin thoroughly with water; rapidity in washing is most important in reducing extent of injury.

Eye Contamination

1. Hold eyelids open, wash eyes thoroughly with gentle stream of running water immediately. Delay of few seconds greatly increases extent of injury.
2. Continue washing until physician arrives.
3. Do not use chemicals; they may increase extent of injury.

Injected Poisons (scorpion and snake bites)

1. Make patient lie down as soon as possible.
2. Do not give alcohol in any form.
3. Apply constricting bend above injection site (e.g., between arm or leg and heart). The pulse in vessels below the constricting bend should not disappear, nor should the constricting bend produce a throbbing sensation. The constricting bend should be loosened for 1 minute every 15 minutes.
4. Apply ice-pack to the site of the bite.
5. Carry patient to physician or hospital; *do not let him walk.*

Accidents—Control of Bleeding

The nurse will follow the accepted procedures described in the American Red Cross First Aid Handbook. Medical care should be arranged for immediately.

Other Standing Orders

Some agencies may wish to adopt other standing orders in relation to foot care for the diabetic and elderly; decubitus ulcers, impactions, etc.

Heberden's Syndrome

Precordial, substernal, epigastric, or occasionally jaw area pain which originates from spasm or partial atheromatous occlusion of one of the coronary arteries was described first by Heberden as angina pectoris in 1785.

The discomfort of angina pectoris varies from a mild sensation of weight or pressure felt after exertion or following meals to severe recurrent paroxysms, which may eventually appear while resting or sleeping. This latter type is particularly characteristic of preinfarction anginal syndrome. The pain of true angina pectoris may radiate to the anterior shoulder area, the inner aspect of the arm, the anterolateral portion of the neck, or just above the angle of the jaw. Long continued or severe attacks are often followed by coronary occlusion and myocardial infarction.

Angina pectoris should be differentiated from pseudoangina, anterior chest wall pain, and hiatus hernia. An electrocardiograph may give evidence of coronary disease; if not, a two-step exercise curve may be diagnostic. Immediate pain relief may usually be obtained by nitrites; however, if myocardial infarction supervenes, the value of nitrites is sharply limited. If severe angina pectoris is recurrent the prophylactic use of anticoagulants is indicated.

MARSHALL, MINNESOTA. Population 7600. Doctors' Plaza needs a fourth practitioner in their group. Salary the first year; then partnership opportunity. Excellent office facilities. Professional Management Services. Accredited hospital within 1½ blocks. Progressive community. New state college to open in September, 1967. Immediate opening. If interested, contact Doctors' Plaza, 903 E. College Drive, Marshall, Minnesota 56258. Telephone 507 532-4416.

INTERNIST, PEDIATRICIAN AND OB-GYNECOLOGIST wanted to join two general surgeons in a rapidly growing practice. Attractive town of 3,000 on large lake 30 miles west of Twin Cities. New 55-bed JCAH hospital with plans for major expansion. Five other physicians in town. No Ob-Gyn., internist, or pediatrician in area. Medical community serves in an area with population of 20-25,000. Planning to expand into partnership multi-specialty clinic. Call or write: Savaryn Clinic, Waconia, Minn. 55387. Telephone: 442-2137.

INTERNIST ASSOCIATE wanted in Pacific Northwest city of 170,000. Low humidity, no ragweed, fabulous recreational area. Expanding practice to accommodate second internist. New multi-specialty building adjacent new hospital in residential area. All hospitals open staff. Further details by correspondence only. Give curriculum vitae first letter. Write: MINNESOTA MEDICINE—382, 496 Lowry Medical Arts Building, St. Paul 55102.

GENERAL PRACTITIONER desires position with group or partnership in town of 3,000 population or more, preferably within 100 miles radius of Twin Cities. Currently in solo practice including surgery and OB at same location for 12 years. Write: MINNESOTA MEDICINE—383, 496 Lowry Medical Arts Building, St. Paul 55102.

IDEAL LOCATION IN SOUTHDAL MEDICAL BUILDING for either primary office or suburban location. Partially furnished and available immediately. Contact: O. A. Schultz, Park Plaza State Bank, phone 935-2141, St. Louis Park.

GENERAL PRACTICE AVAILABLE NORTH CENTRAL MINNESOTA. Well equipped office. New hospital in town. Good records. Terms could be arranged like rent. Write: MINNESOTA MEDICINE—384, 496 Lowry Medical Arts Building, St. Paul 55102.

IDEAL SPACE AVAILABLE. New modern building, ideal location Como Avenue, St. Paul University Campus. Will partition to your specifications. Call 644-5742 or 646-3933, St. Paul.

GENERAL PRACTITIONER wanted to join well established practitioner. Located 65 miles north of Minneapolis-St. Paul area. Population over 3,000. Hospital in town. Good schools, churches, and fine fishing and recreational area. Contact: A. C. Peterson, M.D., 200 E. Forest St., Mora, Minnesota 55051.

FOR RENT: Modern suburban office space now available, with large private parking area, on South Robert near Signal Hills. Successfully occupied by doctors for last twenty-five years. Newly remodeled. Reasonable Rent. 950 South Robert. Telephone: 224-7913, St. Paul.

FOR SALE: 1000 Ft. LAKESHORE located on Big Marine Lake, 28 miles from downtown St. Paul, two level home, 20 ft. living room with marble fireplace facing the lake and the many pine and birch trees. Kitchen with birch cabinets and pecan paneling. Lake-view and dining space, all glass family room, two bedrooms and bath, lower floor has paneled recreation room, with fireplace, second kitchen, bath and shower, laundry room. SECOND HOME—1½ story, full bath, family room, bedroom and fireplace. THIRD HOME is a summer cottage, 24x24 garage, all buildings cedar log siding, bath house on the beach, two wells plus patios. Price: \$49,000.00 Ideal camp site for church, scouts or lodge. For appointment call 297-3320—owner: Russell Stendal.

WANTED: General Practitioner, general surgeon, obstetrician for active group clinic in Minneapolis suburb. Now six man group including full-time surgeon and obstetrician. New clinic facilities and two new hospitals nearby. Salary open. Partnership offered after short trial period.—Coon Rapids Clinic, 9920 Zilla Street N.W., Coon Rapids, Minnesota 55433.

GENERAL PRACTITIONER WANTED: To associate with Physician-Surgeon in Owatonna, A Southern Minnesota community, 25,000 population. Clinic building three years old; with five large treatment rooms; lab.; x-ray; central supply; two doctors' offices; pharmacy; and business offices. Located next door to 85 bed City Hospital. Good opportunity for partnership. Contact: O. W. Roberts, M.D.; 920 So. Cedar St., Owatonna, Minn. Phone 451-4630.

GENERAL PRACTITIONERS AND INTERNISTS to join eight-man group in fascinating San Francisco. Locum tenens also available. Will meet reasonable salary request. A. J. Franz, M.D., 3620 Army St., San Francisco, Calif. 94110.

A man of sixty has spent twenty years in bed and over three years in eating.

Arnold Bennett

Minnesota Medicine at a Glance

Gastric Duplication—Katz et al.

Page 1175

Gastric duplication is a rare congenital anomaly which can be suspected by x-ray and proven only by surgery. The present case describes a rare type of duplication lined with fundic mucosa, arising from the pancreas and communicating with the pylorus and the gastric antrum. This patient had signs and symptoms of acute pancreatitis and chronic intermittent duodenal obstruction. The surgical problem was solved successfully by internal drainage.

Cardiac and Pulmonary Dyspnea—Dines and Parkin

Page 1181

The recognition and differentiation of cardiac dyspnea in contrast to dyspnea due to primary pulmonary disease is an important clinical problem and directly affects the type of treatment instituted. The authors present representative cases illustrating the two types of dyspnea, and outline means of differentiating one from the other. In general, the correct diagnosis is established on clinical grounds; electrocardiographic, x-ray, and pulmonary function studies are used to substantiate the clinical diagnosis.

Cartilaginous Tumors of the Larynx—Gasior and ReMine

Page 1197

An unusual case of chondrosarcoma of the larynx is described in which the patient noted the slow growth of a lateral neck mass of ten years, before surgical removal was accomplished. The literature on this subject is reviewed.

Typical, Atypical and Imitators of Patent Ductus Arteriosus—Lynch

Page 1207

The symptoms, physical signs, and management of the usual (typical) and the unusual (atypical) forms of patent ductus arteriosus vary according to the abnormal physiology produced. In infants, the patent ductus arteriosus is more difficult to recognize than in adults. Surgical closure, even at an early age, is the treatment of choice if the pathophysiology and the status of the pulmonary vasculature permit. Other vascular lesions may mimic a patent ductus arteriosus. Cardiac catheterization and angiography will aid in the differentiation.

MINNESOTA MEDICINE Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Golden Anniversary

Dilantin®

(diphenylhydantoin)

PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.

DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anti-convulsant drugs.

PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. **ADVERSE**

REACTIONS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred. DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.

Parke, Davis & Company, Detroit, Michigan 48232

The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

PARKE-DAVIS

LACTINEX[®]

TABLETS & GRANULES

■ to help restore and stabilize
the intestinal flora

■ for fever blisters and canker
sores of herpetic origin

LACTINEX contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

First introduced to help restore the flora of the intestinal tract in infants and adults,^{1, 2, 3, 4} LACTINEX has also been shown to be useful in the treatment of fever blisters and canker sores of herpetic origin.^{5, 6, 7, 8}

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

In peptic ulcer... antacid therapy with a new benefit

CONTAINS A BALANCED
COMBINATION
OF THE MOST WIDELY
USED ANTACIDS—
FOR RAPID
NEUTRALIZATION.
PLUS SIMETHICONE—
TO CONTROL
THE FACTOR WHICH
ANTACIDS ALONE
CANNOT INFLUENCE.

Mylanta[®]

- In Mylanta, aluminum and magnesium hydroxides are balanced to minimize the chance of constipation or laxation and still achieve rapid acid neutralization and pain relief.
- The positive action of simethicone helps relieve the painful gas symptoms which often accompany the peptic ulcer syndrome.
- The nonfatiguing flavor and smooth, nongritty consistency of tablets and liquid encourage continued patient cooperation during long-term therapy.

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) of liquid contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. **Dosage:** one or two tablets, well chewed or allowed to dissolve in the mouth, or one or two teaspoonfuls of liquid to be taken between meals and at bedtime.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Picture of painful myositis

**Parafon Forte helps to relieve pain,
restore mobility . . . stop pain-spasm feedback**

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 6-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds.

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.

Tylenol® (acetaminophen) 300 mg.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light-headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied:** Scored, light green tablets, imprinted "McNEIL"—bottles of 100.

McNEIL

*U. S. PATENT NO. 2,895,877
MCNEIL LABORATORIES, INC., FORT WASHINGTON, PA.

President's Letter

IN JUNE, 1967, I was privileged to attend an AMPC workshop in Washington, D. C., an even better one than I attended last year. The attending physicians and their wives were supposed to be those most interested in political affairs in their respective states: a hand-picked group, as it were. We were asked to fill out a ballot on preference for President of the United States, as of that particular day, as well as to predict who would be on the Republican and Democratic National Tickets for President and Vice President in 1968. The result of the voting is immaterial. *The real shocker came when our chairman announced that only 47% of those present had bothered to fill out their ballots and turn them in.* And this happened in a meeting of supposedly politically astute and discriminating people. (Yes, I voted!!). I was ashamed of them!!

If we lose our precious political heritage, it will be by default. *We couldn't be bothered!* I want to pass on just a few statistics to you (I don't especially like them either) which really rocked me!

Did You Know That—only 3% of our population work for the candidates for either party? 97% don't want to be bothered!!

Did You Know That—91% had not been contacted to register by either party?

Did You Know That—89% had not been contacted to get to the polls on election day?

Did You Know That—88% had not been asked by either party for contributions?

Did You Know That—76% had not been asked to support candidates of either party?

And Finally, Did You Know That—31% had received no literature from either party?

I know that not everyone can be interested in politics, but certainly, with the educational background each physician (and usually his wife) has, we should be willing to assume positions of leadership in our communities. There are School Boards, Church Boards, Chambers of Commerce Boards, Kiwanis, Rotary, Lions, Women's Clubs (you know the list) that we and our wives can participate in.

Someone has said, "If we are unwilling to participate in the affairs of government, we must then be willing to be governed by less capable persons than ourselves." I want to "point with pride" to one of our County Medical Societies, the Southwestern Minnesota Society. Forty-four physicians out of 54 in that society supported NUHOPE financially. They also promoted the party of their choice. Almost 100% of us physicians are in a favored economic position and can well afford to support not only our own favorite political party and NUHOPE as well; but we can also go further and support generously some of our personal friends who may happen to be candidates.

This doesn't mean that we *Buy These Parties or Candidates!* We can't put them in a straight-jacket just because we have contributed to them; nor is it always even wise to have it known publicly that we support specific candidates financially. **BUT SUPPORT THEM WE SHOULD!!** How much should you give? Only you can tell; but most physicians can easily afford to contribute \$25.00 for themselves, and \$25.00 for their wives to NUHOPE, plus \$100.00 **MINIMUM** to the party of their choice. Most physicians don't have time to engage in political activity; but consider

Continued to Page 1338.

easy does it!

tear, moisten, compare—that's all!

Enteropathogenic *Escherichia* *Coli* in Children

GERALD M. NEEDHAM, Ph.D.*

JAMES E. WENZL, M.D.**

Rochester, Minnesota

SALMONELLA AND SHIGELLA have long been recognized as agents causing enteric disease, but the role of *Escherichia coli* as an etiologic agent in diarrheal disease, especially in children, has been controversial. Study of the relationship of certain *E. coli* serotypes to infantile gastroenteritis became possible when Kauffman worked out a serologic differentiation. Since there are more than 140 serogroups and many additional serotypes, biochemical tests by themselves were inadequate to differentiate the strains. Subsequently, only a few of the serotypes of *E. coli* were found to be associated with gastroenteritis. These serotypes collectively have been named "enteropathogenic *Escherichia coli*."

Enteropathogenic *Escherichia coli* have been incriminated as causative agents of both sporadic and epidemic gastroenteritis in infants, especially of epidemic diarrhea of the newborn. In infants the mortality of epidemic diarrhea due to enteropathogenic *Escherichia coli* has been reported to be as high as 50%.¹ In other studies, enteropathogenic *Escherichia coli* have been isolated from the stools of full-term and premature newborn infants who were entirely asymptomatic.^{2,3}

Sporadically occurring diarrheal illness due to enteropathogenic *Escherichia coli* appears to be less severe than similar infection seen under epidemic conditions. On the basis of hospital admissions for diarrhea, the reported incidence of sporadically occurring enteropathogenic *Escherichia coli* diarrheal illness in North American infants and children varied from 2.6%⁴ to 45%.⁵ This difference reflects regional variations in both disease prevalence and detection, as well as differences in the age groups surveyed. Table 1 shows the reported incidence of enteropathogenic *Escherichia coli* isolations from the stools of North American infants and children with sporadically occurring diarrhea. The reported incidence is lower for the more northern latitudes and higher for the southern states and Puerto Rico.

This study was designed to test our observation that gastroenteritis due to enteropathogenic* *Escherichia coli* in infants and children seen at the Mayo Clinic was relatively uncommon. We reviewed the results of all stool cultures obtained from infants and children during a 2½-year period, and the medical records of all children with positive cultures for enteropathogenic *Escherichia coli* to define the illness, if any, associated with these organisms.

Materials and Methods

We analyzed 412 consecutive cultures of stool specimens from infants and children, both inpatients and outpatients, chiefly the latter. The period of study extended from June 1, 1964, through December 31, 1966. During this time there were no known epidemics of bacterial enteropathogens. The great majority of stool cultures were obtained because of diarrhea. How-

ever, it was not routine practice to obtain stool cultures on all outpatients with diarrhea; in each case the decision was made by the individual physician.

Specimens were obtained for bacteriologic examination from freshly passed stool or by rectal swab. Fecal material was emulsified in a few milliliters of nutrient broth before culturing, whereas material on rectal swabs was inoculated directly onto the various media. All specimens were cultured for enteropathogenic *Escherichia coli* on blood agar plates and on eosin methylene-blue plates. Media specific for isolating *Salmonella* and *Shigella* were also inoculated.

After incubation for 24 hours at 37 C., 10 typical *E. coli* colonies were selected and transferred to a nutrient agar slant. A presumptive screening test was performed based on the reaction of growth from the agar slant with polyvalent OB antisera. Cultures agglutinating with specific *E. coli* OB antisera in the presumptive screening test were confirmed by means of specific *E. coli* O antisera, as follows: growth from the slant was washed off in 0.85% sodium chloride and heated in a boiling water bath for 30 minutes; after the addition of formalin to give a final concentration of 0.5%, the density was adjusted to equal a McFarland Standard No. 3; and serial dilutions of the specific *E. coli* O antisera plus aliquots of the heated bacterial suspension were incubated in a water bath at 50 C. for 18 to 20 hours. Cultures showing agglutinations in dilutions of 1:320 or greater were considered to have the same O antigen as the antisera. This constituted a final serodagnosis.

Organisms considered to be *Salmonella* or *Shigella* were identified by the usual biochemical and serologic procedures.

Results

Enteropathogenic bacteria were isolated from 32 of the 412 cultures, an incidence of 7.7%. *Salmonella* organisms other than *Salmonella typhosa* were isolated in 14 cases (3.4%). No *Shigella* organisms were isolated, and enteropathogenic *Escherichia coli* were isolated in the remaining 18 cases (4.3%). In no instance was more than one enteropathogenic bacterium isolated from the same patient. Table 2 lists pertinent clinical data on the 18 patients from whom the enteropathogenic *Escherichia coli* were isolated.

No predominant serotype of enteropathogenic

Escherichia coli was isolated during the period of study. Types 026:B6, 0111:B4, and 0128:B12 accounted for 13 of the 18 isolations.

All patients were Caucasian and 17 were from the immediate vicinity of Rochester, Minnesota. Also, 12 of the 18 patients were girls. The mean age of boys was 29.5 months and of girls 8.3 months.

Fifteen of the 18 cases occurred from June through September. This may reflect only the increased incidence of viral and nonspecific diarrheas during these months and the consequent increase in the number of stools submitted for culture. During the 2½-year period of study, no enteropathogenic *Escherichia coli* isolations were made from January through April.

Diarrhea was present in 15 of the 18 cases and was the most constant symptom. In no case were the stools said to contain gross blood or excessive mucus. The pattern of diarrhea was not distinguishable from that of nonbacterial diarrhea. Two of the patients who had no diarrhea had vomiting. Seven patients had a temperature of more than 100 F. on initial examination. One asymptomatic boy was discovered to harbor enteropathogenic *Escherichia coli* during a familial contact study occasioned by the isolation of *Salmonella typhimurium* from one of his siblings.

Symptoms were analyzed and estimated to be mild, moderate, or severe: mild, if the patient had vomiting, diarrhea, or both, and showed a favorable response to supportive therapy, consisting primarily of dietary measures; moderate, if the patient received parenteral fluids electively; and severe, if life-threatening dehydration required administration of parenteral fluids. Thirteen patients were judged to have a mild, three a moderate, and one a severe illness. None of those with mild illnesses were treated with antibiotics until after isolation of the enteropathogenic *Escherichia coli* from the stool, usually three to four days after submission of the stool to the laboratory for examination.

Seven patients received antibiotic therapy, six by the oral route. One patient received ampicillin and four neomycin. All were free of symptoms within 72 hours. One patient receiving neomycin continued to have moderate diarrhea after 72 hours. The diarrhea subsided within 24 hours after beginning treatment with demethylchlortetracycline. The seventh patient received intravenous fluids and intravenous chlorampheni-

col; his symptoms regressed within 48 hours. In none of the seven cases could the relief of symptoms be proven to result from antibiotic treatment.

Of the 18 patients, seven (39%) had significant coexisting chronic disease. Six of these seven were girls whose mean age was nine months; this compares with a mean age of 7.5 months for the six girls without coexistent disease. Four of the seven patients had been hospitalized for treatment of the coexisting disease in the month preceding the onset of gastroenteritis symptoms.

Comment

Certain aspects of this study merit further comment. Finding eight of 18 affected children to be less than six months of age is consistent with current concepts of the most susceptible population.^{1,3} Finding 12 of the 18 patients to be female probably has no significance since larger studies have shown a slight preponderance of males.^{7,10} The apparent seasonal incidence may reflect only the greater number of stools cultured during this period of greatest diarrheal occurrence, since other investigators have emphasized the nonseasonal occurrence of enteropathogenic *Escherichia coli*. The occurrence of diarrhea in 15 of 18 cases may reflect case selection as well as symptomatology, since diarrhea is the commonest indication for obtaining a stool culture.

The occurrence of enteropathogenic *Escherichia coli* organisms in infants or children with significant coexistent medical conditions has been emphasized by others.^{1,3} Whether the organisms in those cases were true "opportunists" or were discovered only because of more intensive medical surveillance of known susceptible subjects is open to question. The finding of an increased incidence of enteropathogenic *Escherichia coli* in association with coexistent disease may reflect increased host susceptibility or increased exposure

to hospital organisms during diagnosis and treatment of the coexistent disease.

Without studies to delineate the asymptomatic carrier state in this community, it is difficult to determine the significance of the isolation of these organisms. That 13 of the 18 subjects experienced a mild illness and that eight of the 13 recovered without receiving antibiotic therapy would suggest, that sporadically occurring enteropathogenic *Escherichia coli* organisms were of minor pathogenic significance in this area during the period of this study. Solomon and co-workers¹⁴ in Boston studied 1,078 pediatric patients without diarrhea and found the asymptomatic carrier rate to be 4.7%. They concluded that the frequency of the asymptomatic carrier rate of enteropathogenic *Escherichia coli* makes it impossible to attach causal significance to the isolation of strains of this organism in sporadic episodes of diarrhea. We agree and would emphasize that not all patients with enteropathogenic *Escherichia coli* require specific antibiotic therapy.

Summary

Four hundred twelve consecutive cultures of stool specimens from infants and children with diarrhea were studied for the presence of enteropathogenic *Escherichia coli*. Eighteen positive cultures were found, an incidence of 4.3%. Eight of the 18 patients were less than six months old. The clinical severity of symptoms was mild in 13 cases, moderate in three, and severe in one case. One boy was asymptomatic. Only seven patients received specific antibiotic therapy.

The incidence of sporadic gastroenteritis associated with enteropathogenic *Escherichia coli* was low in this area during the 2½-year period of study. In the absence of a total community study to determine the asymptomatic carrier state, it is not possible to assess the pathogenicity of enteropathogenic *Escherichia coli* in sporadic gastroenteritis associated with it.

Generalized Renal Cystic Disease in Children*

ROGER C. HERDMAN, M.D.**
Minneapolis, Minnesota

RENAL DISEASE in children characterized by generalized cystic dilation of the tubules often involves the physician in difficulties of identification, management, prognosis and family counseling. Yet in the confusing body of literature dealing with cystic kidneys there is available information to allow one to isolate and identify many clear-cut pathological and clinical entities and, having done so, to give prognoses and genetic counseling. Recent studies have also suggested reasonable hypotheses to explain the existence and/or development of cystic tubular disease.

Cystic Diseases of the Kidney

Some of the available material is here presented in hope that it may be useful both in practical identification and handling of cystic diseases and in conceptual† thinking of etiology. The table is a list of readily identified cystic diseases. These conditions are discussed below.

Infantile Polycystic Kidney

Infantile polycystic disease is an autosomal recessive condition occurring in infants and progressing to death generally in a matter of hours or days.¹ This disease is characterized by great enlargement of the kidneys, occasionally sufficient to cause dystocia. However, since the cysts are small (1-2mm.), the kidneys are smooth, normally contoured and not lumpy on palpation. The pathological characteristics are sponge-like (Figure 1) cystic dilation of the collecting ducts involving both cortex and medulla, minimal or no increase in connective tissue, and the presence of normal-appearing nephrons (occasionally a small rim of cortex) among the dilated tubules. There is associated bile duct proliferation and cystic changes in the liver and occasionally in the pancreas or lung, but these changes are often of no clinical importance. The clinical findings (large smooth kidney), course (rapidly lethal), pathology (evenly cystic distal nephrons without

dysplasia), and inheritance (autosomal recessive) allow precise identification of this disease.

Microcystic Kidney

Cystic dilation of the proximal tubule may develop during the course of infantile or congenital nephrosis. Unrelenting proteinuria resistant to therapy and progressive renal failure characterize this disease, which is probably primarily due to a glomerular abnormality. When associated with

prematurity and placental enlargement it is an autosomal recessive condition. Infantile nephrotic syndrome is uniformly fatal unless it can be established that it is secondary to some toxin such as mercury.²

The cystic features must be considered at present as only an interesting pathological finding. They are limited to the cortex (Figure 2), and early in the disease the remainder of the kidney is little changed. The importance of this condition lies not in the cystic tubular changes but in the glomerular abnormality which leads to development of nephrosis.

Cystic Kidney With Congenital Hepatic Fibrosis

Renal tubular ectasia with congenital hepatic fibrosis is an autosomal recessive condition. Large kidneys which show collecting tubule ectasia by pyelography (Figure 3) are associated with liver disease characterized by periportal fibrosis and bile duct proliferation (Figure 4). Patients may present with primarily liver disease—hepatomegaly, cirrhosis, and portal hypertension with varices—or renal disease and arterial hypertension. The distinctive features of the renal disease are enlargement of the kidneys, small cystic tubular dilations in both cortex and medulla, increased connective tissue and progressive glomerular obsolescence (Figure 5). Depending on the stage of the disease, areas with normal glomerular architecture are observed (Figure 6). Many children present with hematemesis due to varices, and the renal disease is discovered incidentally. Prognosis needs to be individualized. While some children die in infancy, others may be asymptomatic and only discovered in families surveyed by pyelography. A period of observation is necessary to determine the rate of progression of the disease, since the children may survive into adulthood.

Multicystic Kidney

When unilateral, a multicystic kidney usually presents as an asymptomatic lumpy mass. The kidney itself is generally enlarged and consists of a nubbin of connective tissue with a few dysplastic nephric elements surmounted by a grape-like mass of large cysts. The findings which allow easy delineation of this entity are the absence of any normal nephron elements, the absence of a renal pelvis, and the almost universal association of ureteral abnormalities, generally atresia

at the hilum. This abnormality is not inherited. There is little evidence that multicystic kidneys need to be removed. Aside from occasional gastrointestinal symptoms due to compression and a case of possible malignant degeneration in a woman in her sixties, they are asymptomatic and benign. The physician's efforts should be bent almost exclusively toward careful examination of the contralateral kidney where correctable obstructive uropathy is reported in as high as 70% of cases.³

Medullary Sponge Kidney

This condition is reported almost exclusively in adults.⁴ However, several case reports in children are available including a description of the classical pathology in an infant.⁵ Furthermore, many radiologists have collected pyelograms in children demonstrating the typical fan-shaped dilated collecting ducts opacified with radiopaque medium occurring in several or all the pyramids. This syndrome is not inherited except when associated with Ehlers-Danlos syndrome*, a dominant condition. Because the disease is limited entirely to the medulla, glomerular function is unimpaired. It is important for the physician to keep this condition in mind since the dilatation of the collecting ducts may progress to small cysts in which concretions may form with subsequent hematuria and/or pyelonephritis. In children, however, this disease must be considered an

interesting but benign structural malformation.

Cystic Disease of the Renal Medulla

Cystic disease of the renal medulla or juvenile familial nephronophthisis, an interesting condition known by both the above names, has been convincingly reported as autosomal recessive⁶ and dominant.⁷ We can suspect this disease in a child who develops polyuria, a nephrogenic defect in concentrating ability, suffers a loss in glomerular function and has a normal urinalysis. Pathologically, the disease is readily recognized. In kidneys which are usually almost normal size, cysts develop in the medulla and, to some extent, in the cortex (Figure 7). The main cortical changes, however, are an increase in connective tissue, round cell infiltration and glomerular obsoles-

Fig. 6—Percutaneous renal biopsy from the 3-year-old sibling of the patient whose pyelogram is pictured in Fig. 3. The kidney architecture and glomeruli are relatively normal although this patient's pyelogram was similar to that seen in Fig. 3. Azocarmine $\times 100$.

Fig. 7—Nephrectomy specimen from a 7-year-old female with cystic disease of the medulla. The cysts are limited almost entirely to the medulla.

cence. No pyelographic changes have ever been observed. Once established clinically, this condition progresses to renal failure in only a few years. It has been described from early childhood to old age.

Cystic Disease Associated with Inherited Syndromes

Renal disease with cystic components can be classified also when associated with other well-defined syndromes. Examples of this are functioning distal nephron cysts observed in the thoracic asphyxiant syndrome,⁸ a recessive condition which generally has terminated fatally in early childhood due to respiratory disease or uremia, and the association of radiologic evidence of medullary sponge kidney with Ehlers Danlos syndrome.

Diverse Polycystic and Cystic Dysplastic Kidneys

Cysts in any single or multiple areas of the nephron from Bowman's capsule to the collecting duct have been identified in unilateral or bilateral forms of cystic disease in children.⁹ Grossly the pathology ranges from large kidneys identical in appearance to adult late-onset dominant polycystic disease to small dysplastic organs with scattered cystic areas. Often anomalies of other organs are present. Microscopically cystic areas, increased connective tissue, dysplastic or obsolescent nephrons, thickened vasculature, cartilage and smooth muscle, nests of adrenal tissue and the like are found in varying degree. Such kidneys have been identified at ages from the first day of life to older childhood. Occasionally several children with polycystic kidneys in this group are found in one family, implying an autosomal recessive inheritance. The course of disease in such patients varies from rapid fatality (often a result of the associated anomalies) to prolonged periods of well being.

We have observed a child with larger bilateral polycystic kidneys diagnosed in infancy who remains well without azotemia or hypertension twelve years later, although it is generally true that the younger the patient the worse the prognosis. At present, these cystic organs are difficult to separate into meaningful groups; such cases are usually grouped together under the heading polycystic kidneys, undefined type, the prognosis becoming apparent after observation for a time or remaining uncertain.

Laboratory Data

There is relatively little laboratory information which can be brought to bear on differentiating cystic diseases. Routine urinalysis usually is remarkable mainly for its relative normalcy.

Proteinuria and Hematuria

Severe proteinuria occurs in microcystic disease associated with infantile nephrosis, but in most other cystic diseases there is usually no or minimal proteinuria. Formed elements vary in type and quantity with the stage of disease and from case to case but generally are not prominent. It is not meant to imply that severe proteinuria and hematuria do not occur in cystic diseases, but they are the exception rather than the rule.

Concentrating Ability

Glycosuria is seen in scattered instances of some forms of cystic disease such as undefined polycystic kidney or microcystic disease. Limita-

tion of concentrating ability is an early hallmark of cystic disease of the renal medulla, and minor defects in concentrating ability occur early in other conditions such as cystic disease associated with congenital hepatic fibrosis and medullary sponge kidney. Defects in ability to acidify the urine have also been reported in cystic disease of the renal medulla and medullary sponge kidney, but these are not of metabolic significance. Other tubular abnormalities such as salt wasting and amino aciduria are reported in scattered instances but are not considered pathognomonic of any form of cystic disease. Loss of glomerular filtration rate with uremia and associated abnormalities of acid-base and calcium and phosphorus homeostasis occur eventually in all forms of cystic disease described above with the exception of medullary sponge kidney.

Biopsy

Renal biopsy may occasionally be of assistance

Fig. 8—A schematic presentation, taken from data of Osathanondh and Potter, of human embryonic renal development. Consecutive branching of the ureteral bud, expansion of generations of branches to form the pelvis perhaps due to pressure of urine formed by nephrons newly induced by ampullae, further nephron generation, and some degeneration of early nephrons attached to branches which expand to form calyces, and finally continued budding and nephron induction schematically shown.

in diagnosis. It has helped us in cystic disease of the medulla and microcystic disease, and it is sometimes useful in assessing the stage of the disease and in investigational work. In general, to obtain adequate tissue, open, rather than percutaneous biopsy is carried out if the kidney is involved with large cysts. In our opinion such kidneys with increased connective tissue and thick, poorly contractile vessels which may be close to each other around cysts deserve open biopsy for adequate hemostasis.

Hypertension

As a rule, hypertension occurs only late in the course of cystic disease of the renal medulla or microcystic disease and does not occur in medullary sponge kidney unless pyelonephritis has supervened or in multicystic kidney unless the contralateral organ is abnormal. Other forms of cystic disease may be associated with early onset of increased blood pressure.

Comments

At present, therefore, the clinician can classify his material on the basis of family history (if any), age of onset, intravenous pyelographic picture (or retrograde pyelogram for multicystic kidney) of kidney size and contour, associated abnormalities, some clinical and laboratory data, and occasionally renal biopsy.

It is helpful in considering cystic diseases to be familiar with some of the more recent thoughts on etiology. As a background, Figure 8 composed from data of Osathanondh and Potter¹⁰ summarizes facets of embryonic renal development. In brief, an extension of the mesonephric duct invades metanephric tissue where it branches and proliferates; its distal ends (ampullae) organize nephrons and its interstitial tubular segments grow and expand to form parts of the collecting system. One can visualize¹¹ that, if ampullae are normal, normal nephrons will be developed; but if interstitial segments proliferate excessively, collecting duct ectasia will ensue. The result will

be infantile polycystic kidneys. If ampullae are abnormal, branching and nephron induction are curtailed and interstitial bud growth will lead to cystic structures without attached nephrons. The result will be multicystic kidneys. If both ampullae and interstitial buds are abnormal in varying degree, a variety of forms of cystic renal disease ensue with varying degrees of collecting system ectasia and nephron abnormalities. It is also hypothesized¹¹ that if urinary tract obstruction is present, zones of abnormal nephrons and Bowman's capsular cysts may result. Obstructed cystic kidneys are less homogeneous and therefore are not included in the previous groups of separate entities.

Conclusions

The foregoing does not take into account the development of diffuse cystic tubular disease in previously normal organs such as occurs in certain conditions, e.g., cystic disease of the renal medulla.⁶ In these conditions, it seems reasonable to assume that the kidney responds to tubular cell abnormalities with cyst formation. Undoubtedly many different cellular metabolic defects could generate the same end result just as many glomerular diseases give identical morphologic pictures. This hypothesis could account for the presence of concomitant biliary duct ectasia and renal tubular ectasia by assuming an abnormality in an enzyme system common to both cell lines. The hypothesis is strengthened by the finding of cellular functional abnormalities preceding the development of gross morphologic changes, in experimental cystic diseases, and by the recent discovery that electrolyte abnormalities produce cystic disease in the zone of developing nephrons in normal rabbit neonates.¹² It seems likely that diffuse cystic tubular disease represents a morphological end result of multiple factors. These unknown factors may well involve such things as injury of developing embryonic structures by infectious agents, toxins, obstruction, radiation and metabolic errors, as well as the action of some or all of these on already formed structures in later life.

Bronchial Asthma

Food,
Inhalant,
Drug
and
Chemical
Allergies
in
Its
Etiology

ALBERT H. ROWE, M.D.
ALBERT ROWE, JR., M.D.
Oakland, California

WE ARE CONTINUING to obtain evidence which lends support to the thesis that food, inhalant, drug and chemical allergies are responsible for practically all bronchial asthma and other respiratory clinical allergies.^{1,2,3,4} Data based upon clinical results recorded in our practice indicate that food allergy is the sole cause of respiratory manifestations of allergy in 20 to 40% of all cases. Allergy to pollens as the sole cause is indicated in 3 to 25% according to age and degree of inhalation, the minimum frequency appearing in infancy. Associated food and inhalant allergies, one or the other being dominant, are responsible in 42 to 53%.¹ When these allergies are recognized and controlled, infectant asthma, intrinsic and psychogenic causes assume a minimal role or become non-existent. Hence, we have found that change in location or climate, prolonged sanatorium care or long-term corticosteroid therapy is not required to control bronchial asthma.

History of Asthma Due to Food Allergy

Recurrent Attacks With Nasal Symptoms

It is important to recognize the typical history of bronchial asthma due to food allergy,^{1,2,4} especially in infants and children. The typical history consists of recurrent attacks of asthma often preceded by or associated with nasal symptoms. Vomiting and fever as high as 104°F. may occur. Severe or moderate asthma continues for one to three days. Wheezing and coughing disappear in the subsequent one to five days. We have observed a definite decrease or absence of symptoms in the summer.⁵ When food allergy is not recognized and controlled for several months, the interim relief between recurrent attacks is replaced by moderate coughing and wheezing.

Because of initial nasal symptoms and fever in approximately 50% of these cases, infectant asthma incorrectly becomes suspect by many physicians. Relief of this asthma with our control of food allergy has reduced such possible infectant asthma^{1,2,9} to a minimum or eliminated it entirely. When this typical history is present, control of food allergy relieves the symptoms with

no vaccine therapy, no desensitization to skin-reacting inhalants and no long-term corticosteroid therapy.

Interim Relief Between Attacks

Interim relief between recurrent attacks^{1,2} in the typical history is similar to the refractoriness to injections of an allergen after it has produced anaphylactic shock in the guinea pig. During the patient's attack antibodies to causative foods in the lungs can be assumed to be inactivated by uniting with the blood-borne allergens of the foods. Thus their continued ingestion causes no asthma until the antibodies reaccumulate above an assumed reacting threshold in the lungs. Our study of asthma due to food allergy indicates that food allergy is the usual cause of recurrent cyclic attacks in all ages. Such refractoriness after asthma due to inhalants is rare, as evidenced by continued daily asthma as long as causative pollens or other inhalants are in the air.

Although this typical history occurs in some adults,¹ an equivalent history due to food allergy is more common.

Such asthma is perennial and continues in varying degrees, particularly from 1:00 to 5:00 a.m. and with exercise. Careful interrogation often reveals exaggeration of symptoms every two to four weeks, especially in the fall, winter and early spring when food allergy, we have found, is usually exaggerated.

Emphysema and Chronic Bronchitis

The results we obtain in our practice increasingly substantiate the frequency of inhalant and especially food allergy in the causation of the obstructive symptoms of emphysema and chronic bronchitis. Our patients have been relieved of the invaliding symptoms of emphysema as their allergies, particularly to foods, have been brought under control. We have used minimal or no bronchodilator, corticosteroid and intermittent positive pressure-breathing therapy. Our results indicate that bronchospasm and bronchorrhea are due to uncontrolled allergy rather than to actual destructive changes in the lungs. Twenty patients in whom symptoms of emphysema have been brought under good or excellent control with the study and treatment of allergy especially to foods have shown slight or no improvement in their pulmonary function tests.⁶

This important role of food allergy has been confirmed in a recent contribution in which 60 cases of obstructive emphysema with similar relief are reported. In 42 of these cases the degree of destruction in the lung has been indicated by lung scanning¹⁰ with the use of I¹³¹ in human albumen by vein.

In the recent European symposium⁷ on bronchitis and emphysema the asthmatic predisposition was recognized. A further indication of allergy in the etiology of these diseases is the presence of eosinophiles in the sputum and bronchial tissues of affected individuals.⁷ Herxheimer⁸ states that "most emphysema is bronchial asthma with a different symptomatology." Banyai⁹ concludes that bronchial asthma is a major factor in the obstructive symptoms of emphysema.

Indications of Food Allergy

History

Food allergy is usually suggested in the patient's history. The typical history of asthma^{1,2} due to such allergy must be recognized. Perennial asthma, especially in older patients, evidenced by recurrent exaggeration in the fall, winter and early spring and by decrease of symptoms in the summer, requires study of food allergy. Foods which exaggerate asthma or other clinical manifestations of food allergy may be known to patients.

Dislikes and disagreements for specific foods are due to allergy in 20 to 30%.¹¹

Since diet diaries are rarely accurate,¹ their recording by patients and their analysis by physicians are of questionable help.

Skin Testing

Though scratch tests often fail to reveal any or all foods causing clinical allergy, they are routine in our practice.¹ This procedure is justified by large reactions which often occur to foods causing immediate symptoms. Smaller reactions less frequently indicate clinical allergy, often being non-specific. It is generally agreed that much chronic cumulative food allergy is not indicated by positive skin tests.

The clinical importance of all skin reactions, including the large ones, must be determined by provocation feeding tests, necessarily in the symptom-free patient. Such tests, however, may not correctly incriminate an allergenic food if per-

formed during refractory periods between attacks due to food allergy or during the summer when food allergy is often inactivated.⁵

Failure to realize the fallibility of skin testing with foods in revealing clinical allergy and the continued use of test-negative diets to study such allergy rather than diet-trial explain in large part the unfortunate failure of many allergists and other physicians to recognize the frequent clinical manifestations of food allergy.

It is important to eliminate all cereals in the initial study of food allergy in bronchial allergy. Bakery products are made of soy and potato starch flour according to published recipes.^{1,7} Though allergy to soy does occur, its occurrence is much less frequent than allergy to cereal grains. Diarrhea in infancy from allergy to soy is well known. This led to our inducement of meat packers in 1940 to make strained meat¹⁴ which can be used in a meat-base formula^{14,15} without animal and soy milks and which can be prepared in the home or purchased from Gerber Company.

Occasional allergy to soy in adults was evidenced in one man, in whom chronic asthma and symptoms of obstructive emphysema were not relieved until soy, as well as cereals, milk, egg and other foods were eliminated from his diet.^{1,15} When soy bakery products are distasteful, especially to children, they are omitted. Then potato, tapioca, sugar, along with milk-free butter,^{1,7} are increased to maintain nutrition and weight. Provocation tests with other foods are made when relief occurs, as advised above.

Intradermal tests with foods are not used routinely in our work. Many reactions, especially with the intradermal method, are due to irritants in the food extracts. Death, moreover, has been reported from intradermal tests with foods.^{12,13}

Control of Food Allergy

When food allergy is indicated, our cereal-free elimination diet^{1,3,15} is ordered on the first conference in office or hospital. Since test-negative diets rarely reveal or control food allergy, they are not used.

Elimination of Asthma-Producing Foods

Good results from this diet depend on the initial total elimination of all cereal grains including wheat, as well as of the most frequent food

to cause asthma—milk, and also of egg, chocolate, fish, coffee and less allergenic foods. Patients must be given a list of allowed foods including a milk-free hydrogenated* soy oil as a butter substitute.¹⁵ They should be supplied with menus and recipes for soy-potato bakery products. Bakery products must be made at home or bought from reliable bakers who are supervised by the physician.^{1,15} We have found that gluten or even small amounts of wheat, not listed on the label, in bakery products prevent relief in wheat-sensitive patients.¹⁷ Maintenance of nutrition and desired weight is mandatory.

Provocative Tests

The strict initial diet must be maintained until two expected attacks of asthma have not occurred in the fall to late spring or until perennial symptoms have been relieved for one to two months. Then, provocation tests with additional vegetables and fruits, each to be added every two to four days, and later with separate cereals, egg, coffee, milk and other foods are indicated. If symptoms recur without breaks in the diet, foods added in the preceding one to two weeks must be excluded.

It must be remembered that foods tolerated in the summer may cause symptoms in other seasons.⁵ Food allergy often causes recurrent "colds," chronic bronchitis or bronchial asthma during the fall, winter and spring. When allergenic foods have been eliminated for one to three years, lasting tolerance may arise to some or all foods, especially in children. This tolerance occurs infrequently in adults.

Hypodermic desensitization to foods has failed.

Diagnosis and Control of Inhalant Allergy

Inhalant allergy is indicated by asthma during pollen seasons or from animal emanations, dusts, fungi or other air-borne allergens.¹ Though it is a sole cause of asthma less frequently than food allergy, it has been associated with food allergy in approximately 42 to 53% of our cases.

When suspected, initial scratch tests with all important inhalant allergens should be routine. Intradermal tests may be omitted, but if done, they should be performed only with inhalants which have given negative or one plus scratch tests. They should not be done with cottonseed

*See Test Your Word Score Page 1359.

or flaxseed, or with dilutions stronger than 1 to 500.¹ As with foods, all positive inhalant reactions do not indicate clinical allergy. History or provocative inhalant tests must determine their allergenicity. Thus, reactions to trees, grasses and fall pollens may occur in a patient allergic only to the fall pollens. Desensitization too often is given empirically with pollens, fungi, dusts, or other inhalants for months or years with no relief to patients suffering with unrecognized food allergy alone.

Treatment of Inhalant Allergy

Environmental control often relieves allergy to animal emanations, dusts and other allergens in the living or working environments. Efficient pollen and dust filtration reduces or controls resultant symptoms.¹

When the elimination of inhalant allergens is impossible, desensitization to antigens containing the responsible inhalants is indicated.

Drug and Chemical Allergies

Drugs and chemicals as causes of asthma are rare when compared to their role in the production of allergic manifestations in the skin and to a lesser degree in other tissues. Acetylsalicylic acid causes asthma in approximately 3 to 5%¹³ of these cases. It is necessary, of course, to eliminate totally the use of a drug or chemical when its allergenicity has been demonstrated. Though other pain-relieving drugs cause clinical allergy, they infrequently cause asthma. Asthma and fatal anaphylaxis occur from penicillin of all types and occasionally from other drugs.¹ One of our patients developed severe near-fatal asthma three times before tolbutamide was recognized as the cause.

Evidence Against Infectant Asthma

When food allergy is controlled, recurrent nasal symptoms,^{1,2,16} at times accompanied by fever of 101 to 104°F. suggesting an infectious cold, associated with or followed by bronchial asthma, do not occur. Their recurrence in September to November, especially in children, is best explained by activation of food allergy in the fall months.⁵ Tonsillectomy and adenoidectomy, rather than alleviating asthma, may serve to intensify it. When asthma due to food allergy

is controlled, infectious colds do not cause asthma.

We have found that vaccine therapy alone does not control asthma.

Drug Therapy

Until the control of food and/or inhalant allergy relieves asthma, medications are required.^{1,3,4} Epinephrine, 1 to 1000, hypodermically in doses of 0.15 cc. to 0.5 cc. according to age, every one-half to six hours, is most effective. Inhalation of epinephrine 1 to 100, or isuprel 1 to 200, by hand atomizers or by intermittent positive pressure is also justified. Aminophyllin, 2 to 7½ grains, by rectum or by vein after the age of five years, in doses according to age, can be given every eight to 12 hours. Ephedrine and aminophyllin in tablets or suspension relieve moderate asthma.

For severe and intractable asthma large doses of corticosteroids orally or intramuscularly are indicated. The doses are reduced to a minimum or entirely eliminated as the immediate and continued study of inhalant and food allergy controls the symptoms. If corticosteroids have been given previously on a long-term basis, small doses may be required as compensation for impaired adrenal function. When causative allergy has been controlled, long-term corticosteroid therapy has not been required in any child and in only small doses in a small percentage of adults in our practice. Indicated potassium therapy and, if duodenal ulcer is possible, antacid therapy may be advisable. In severe or intractable asthma electrolyte and fluid requirements must be fulfilled.

Mild or moderate asthma from uncontrolled inhalant or food allergy is relieved by small oral doses of ephedrine and aminophyllin. Epinephrine hypodermically or by inhalation or isuprel by mouth or inhalation is also helpful. A brief course of corticosteroid therapy may be advisable. In our practice no long-term intermittent positive pressure has been used. The relief of asthma and of associated emphysema and bronchitis has depended upon control of allergy to inhalants, drugs, chemicals, and especially to foods.

Summary

1. A typical history of bronchial asthma due to food allergy in children and in some young adults, and its equivalent perennial history in adults, must be recognized.

2. Food allergy is observed to be the sole cause of bronchial asthma in approximately 20 to 40% of cases and is associated with inhalant allergy, as a major or minor cause, in an additional 42 to 53%. Inhalant allergy is the sole cause in 3 to 25% according to age.

3. The invaliding symptoms of emphysema and chronic bronchitis decrease even to a minimum with little or no bronchodilator or corticosteroid therapy when atopic allergy to foods, at times associated with inhalant allergy, is controlled. This relief results from control of bronchorrhea and bronchospasm due to atopic allergy. Since little or no improvement in pulmonary function

tests occurs, relief is not due to a decrease in destructive lung disease.

4. Food allergy is studied and controlled with the writers' cereal-free elimination diet.

5. Control of inhalant allergy requires desensitization to allergens unless the causative inhalants can be eliminated from the patient's environment.

6. Until control of food and/or inhalant allergy occurs, symptoms must be relieved by medications, as advised. These medications are also given for asthma arising from subsequent breaks in diet, allergy from drugs, or inadequate control of inhalant allergies.

Ehler-Danlos Syndrome

This disorder is usually familial, congenital and is inherited as an incomplete dominant. It may affect either sex.

It is characterized by hyper-elasticity of the skin, hyper-laxity of the joint, subcutaneous tumor, and fragility of the skin and its blood vessels with faulty healing leading to papyraceous* scar formation. It is frequently associated with other organic disorders. The features of this disease are evident in childhood and persist throughout life. Because of the exceptionally thin and fragile skin, precautions directed towards the prevention of injury should be undertaken.

Heart

Nature is profoundly imperturbable. We may adjust the beating of our hearts to her pendulum if we will and can, but we may be very sure that she will not change the pendulum's rate of going because our hearts are palpitating.

—Oliver Wendell Holmes

Memoirs of a Lady Ambulance Surgeon

Jim, Stockings, Babe, and Don

The old ambulance stable is one of the most fascinating memories of my hospital days, and nothing quite like it exists today. Since the earliest dawn of civilization man has turned to two faithful companions, his horse and his dog, for help in time of stress, either to save his own life or to help him on some errand of mercy.

When you entered the building you could see the stalls with the sleek contented animals, and hear that indefinable crunch of eating good oats, and smell the also indefinable fragrance of hay, plus horse, which one associates with a well kept stable. If you wandered near the stalls, the keen eyes of these trained horses seemed to be taking you in completely with an accurate appraisal.

Remarkable animals they must have been, for today they stand out in memory as sharply as though I had seen them yesterday. There was Jim, white and graceful, distinctly of the racing horse type, and the fastest of them all. High-spirited, sensitive, loyal, Jim would do anything that his master called upon him to do, but he wanted to do his part freely and generously and without coercion. All that was necessary was to take the reins and give a click, and Jim would be off top speed wherever he was directed.

Stockings in the next stall, gave Jim a close brush for first place in our affections, and I do believe that in the heart of at least one of the drivers he held that place. Stockings, though heavier in build, also had tremendous speed; a bay with white feet, he had the uncanny intelligence that could cut corners, and jump children at play, and get you to your destination sound of wind and limb.

Next to him was big and rollicking Babe, well-named in that he lacked mature judgment. I was in only one accident during my entire experience on the ambulance and that was when our casual Babe was taking us down a crowded side street. He encountered a still more casual horse attached to a grocery wagon. They met in a head on collision and we all swung around in a mighty whirl, each driver finding himself heading in the opposite direction. After sorting ourselves out and finding that no one was hurt, we proceeded on our way.

Don occupied the last stall. He was a big, gaunt, surly, iron-gray horse. If he had been a human, you would have been sure that he suffered from chronic indigestion. He was cynical, not vicious, but bored to death to be called upon too often for speed. However, when it was necessary, old Don could get up speed, and when he really went into action he was tremendous with his huge ungainly body plunging along in the crowded streets.

How can I recreate for those who have no memory of it the fascination of those days when New York was a horse-drawn city?

Emily Barringer, M.D.: Bowery to Bellevue, 1950.

It is not open to the cool bystander . . . to set himself up as an impartial judge of events which would never have occurred had he stretched a helping hand in time.

Adversity introduces a man to himself.—Anonymous

Nonspecific Ulcers of the Colon

SIDNEY M. MILLER, M.D.*
Santa Barbara, California

JOHN H. JUHL, M.D.**
Madison, Wisconsin

THE SIMPLE OR nonspecific ulcer of the colon is a relatively rare lesion which occurs much more commonly in the cecum and ascending colon than elsewhere. It may mimic other more common gastrointestinal diseases clinically and be confused with these diseases. Pathologically, it is a simple inflammatory lesion which may be confined to the mucosa and submucosa but has a tendency to penetrate more deeply, leading to perforation. Nonspecific inflammatory reaction is found in the base of the ulcer and there is often a considerable local reaction surrounding the crater, with a tendency to scarring and sometimes contracture leading to partial obstruction. It is unrelated to granulomatous disease of the colon, ulcerative colitis, vascular disease, and infectious disease. No aberrant mucosa has been reported in the area of ulceration. For the most part the literature has been devoid of an adequate description of this entity and there is only a single previously reported case in which the diagnosis was suggested preoperatively.¹

Nonspecific ulcer of the colon was first described by Cruveilhier² in 1830. A review of the literature discloses only 90 cases reported since then (Table 1). Most of the authors suggest that the disease is more common than is generally realized and that it is missed completely or misdiagnosed in many instances. It occurs predominantly in males in a ratio of 2 to 1. The age range is wide, varying from 18 to 80. In males the peak incidence is in the fifth decade, while in females it is in the third decade.³ Approximately 4% of the reported patients were known to have peptic ulcer of the stomach or duodenum.⁴

Clinical Findings

Appendicitis-like Symptoms

In the vast majority of cases pain is the presenting symptom. The pain is quite variable and may be acute; or it may be relatively chronic with

*From the Department of Radiology, University of Wisconsin Medical School, Madison, Wisconsin.

Now at 521 Doyle Park Drive, Santa Barbara, California.

**Department of Radiology, University of Wisconsin Medical Center Madison, Wisconsin.

an insidious onset. In uncomplicated cases the clinical findings often simulate those of appendicitis. There is right lower quadrant pain and tenderness, often with an acute onset but sometimes recurrent and usually unrelated to meals. This clinical picture occurs when the ulcer is in the cecum. In Barlow's series of 78 cases⁴ constipation was reported in 40%. In this group the initial diagnosis was appendicitis in more than two thirds of the patients. Rectal bleeding or melena has been reported in a total of five cases.^{3,5} The bleeding is usually not very serious. The typical clinical picture is altered by complications, the most significant of which is acute perforation. This occurs either into the peritoneal cavity resulting in peritonitis or into the retroperitoneal space causing a retroperitoneal abscess. In single instances the patient presented with an intussusception³ and a subphrenic abscess.⁶

Location of the Ulcer

Nearly two thirds of the ulcers were found proximal to the transverse colon, most commonly in the cecum (44 cases), accounting for the frequent incorrect presumptive diagnosis of appendicitis. The sigmoid colon was involved in 16% of the total cases. This relatively high incidence of ulcers near the ileocecal valve is similar to the situation in the duodenum where ulcers occur beyond the pyloric sphincter where the blood supply is relatively poor according to Cameron.⁷

Perforation

Perforation is an exceedingly common complication, particularly in ulcers involving the left colon. Barlow⁴ found that 81% of the lesions in the left colon had perforated at the time of surgery or autopsy; perforation was slightly less common (66%) in lesions of the proximal colon.

Pathologic Findings

Grossly the ulcer of the colon resembles a peptic ulcer with smooth, punched-out margins or an irregular, sharply raised border, varying in size up to 4 cm. in diameter. The shape also varies and, if elliptical, the long axis may be either longitudinal or circumferential. The crater may extend to the serosa with destruction of the muscle layers and marked overgrowth of the connective tissue resulting in thickening of the contiguous bowel wall. The base is often necrotic and in-

filtrated with inflammatory cells, and there is frequently considerable inflammatory response in the bowel surrounding the ulcer. Multiple ulcers were found in 18 of the 90 cases reported and were invariably situated in close proximity to each other.^{3,4,6,8} The inflammatory reaction was often severe enough to produce pseudotumor; therefore the lesion has been misdiagnosed, surgically, as a carcinoma in a number of instances (e.g., our Case 2).

Roentgenographic Findings

There is very little information in radiologic literature regarding this entity, and in only a single previous case report was the diagnosis sug-

TABLE I
SITES OF NONSPECIFIC ULCERS OF COLON

Fig. 1-a — Initial barium enema showing poor filling of the ascending colon due to spasm. The ulcer is not well visualized and the deformity suggests more extensive disease than is present.

gested preoperatively.¹ In most of the cases in which roentgenographic findings were reported, they tended to be misleading. The spasm usually found in conjunction with the lesion, along with its accompanying poor filling and the irregular appearance of the involved bowel, suggested either carcinoma or tuberculosis in the majority of cases^{4,6,9}

Feldman¹⁰ indicates that the lesions are very difficult to find and suggests the use of double contrast enema to outline the ulcer crater. In summarizing the roentgen signs of nonspecific colon ulcer, he listed the following roentgen signs: (1) a visible ulcer defect, (2) nodular swelling due to edema surrounding the ulcer, (3) localized irritability of the affected portion of the colon, (4) localized hypermotility of the bowel, (5) localized spasm and tenderness, (6) stricture and stenosis due to cicatricial changes, (7) perforation with signs of intraperitoneal air.

Case Reports

Case 1

The patient, a white female, 20 years of age, was ad-

mitted to University Hospitals in April 1965 with symptoms of abdominal pain and melena for the preceding two months.

Past History

The patient, her mother, and two sisters had incontinentia pigmenti, a familial disease with cutaneous and dental abnormalities; and the stigmata of this disease were also apparent on examination.

Her rather involved medical history revealed that she had suffered recurrent episodes of abdominal pain since childhood. These were frequently associated with bloody stools and always responded to conservative treatment. An extensive hospital workup elsewhere in November 1954 included a barium enema and an upper G.I. series with a small-bowel study. These procedures did not reveal the source of her difficulty.

In March 1955 she underwent a laparotomy at another hospital for suspected appendicitis. The appendix was removed but was normal and no other findings were reported. She was again hospitalized in March 1956 following an episode of pain and bloody diarrhea which lasted 24 hours. Again the cause was not determined. In December 1961 she was rehospitalized elsewhere with anemia and a palpable right lower quadrant mass. Tumor was suspected and she was explored. A benign 2-cm. ulceration on the lateral aspect of the cecum, just below the level of the ileocecal valve, was found; and a segment of the cecum measuring approximately $2\frac{1}{2} \times 4$ cm. was removed. This was a wedge type of local resection.

Fig. 1-b—This film was taken 90 minutes after oral administration of barium. The ulcer crater is visible (arrow) and the marked scarring and shortening of the right colon is apparent. The previous resection removed only a small $2\frac{1}{2} \times 4$ -cm. wedge of cecum.

Fig. 1-c—Spot film of the hepatic flexure demonstrates the ulcer to good advantage. Note the scarring as well as redundant folds opposite the crater.

On the present admission the patient stated that she had been well for a time after the surgical procedure.

Physical and Laboratory Findings

There was considerable tenderness to palpation in the right lower quadrant associated with muscle spasm and slight rebound tenderness. Pelvic and proctoscopic examinations were negative. Her hemoglobin was 9.9 grams and the stools were guaiac positive.

Stool examinations for ova and parasites, and cultures for Shigella, Salmonella and Staphylococcus were negative.

Radiographic Studies

Initial radiographic studies in an attempt to find the pathology by barium enema were unsuccessful because of marked tenderness and irritability of the right colon which prevented adequate retrograde filling. It was therefore elected to visualize the colon following oral barium administration. This resulted in satisfactory demonstration of a single ulcer at the hepatic flexure associated with considerable fibrosis and scarring (Figure 1).

Surgical Findings

Because of the extremely chronic nature of the patient's illness and the extent of her present symptoms, surgery was considered necessary, and a right hemicolectomy was performed. At surgery the wall of the ascending colon and hepatic flexure showed generalized thickening. There was a striking foreshortening of the inner aspect of the colon with thick redundant folds on the opposite wall. Induration along the medial aspect prevented palpation of the ulcer. The right colon and 8 cm. of the terminal ileum were removed (Figure 2).

Pathologic Observations

Microscopic examination (Dr. Walter Jaeschke) showed a marked inflammatory reaction composed mainly of

Fig. 2—Photograph of the gross specimen. The ulcer is indicated by the arrow. The surrounding mucosa is normal but somewhat congested. The short attached segment of terminal ileum is also normal.

lymphocytes and plasma cells which infiltrated the entire bowel wall. The base of the ulcer was filled with fibrinous debris, granulation tissue, and acute and chronic inflammatory cells. The regional lymph nodes showed reactive hyperplasia and, in some areas, microabscess formation. There was no evidence of malignancy, and special stains for fungi and acid-fast bacilli were negative.

The patient recovered uneventfully.

Review of the surgical specimen obtained in December 1961 disclosed a similar picture. The ulceration extended nearly to the serosa which was exceedingly congested and inflamed. Lymphocytes and plasma cells predominated with some eosinophils also evident; no epithelioid cells were found and parasites were not identified.

Case 2

The patient, a twenty-five-year-old male, was seen with a chief complaint of right lower quadrant pain.

X-ray Findings

Barium enema examination revealed a large ulcer near the base of the cecum with what appeared to be an associated partially encircling mass deforming the cecum. The ulcer extended medially to the margin of the ileocecal valve. The remainder of the colon and the terminal ileum were normal (Figure 3).

Surgical Observations

The patient was operated upon, and at surgery a rubbery mass was found involving the cecum. The right colon was resected. Grossly it was impossible to tell whether or not the mass was a tumor. On opening the specimen there was gross thickening of the bowel wall. The base of the ulcer was identified; it was yellow-gray in color, obviously necrotic, and the surrounding mucosa was inflamed but otherwise normal. The adjacent serosa appeared congested and covered by granular, thin red exudate. Histologic examination showed only nonspecific ulceration with acute and chronic inflammation and occasional giant cells suggesting a foreign-body reaction. There was no malignancy. Examination of the regional nodes showed only lymphadenitis.

When seen six months later the patient was entirely asymptomatic. A repeat barium enema showed no evidence of recurrent disease.

Discussion

The natural history of the simple colon ulcer may be quite variable. On one hand there may be an acute process with rapid perforation leading to a surgical emergency. In this situation the diagnosis is frequently ruptured appendix or rupture of a diverticulum in a patient with left-sided symptoms which may resemble diverticulitis. In other instances, such as the cases reported here, chronicity and recurrence of symptoms may be present. The radiographic diagnosis has been uncertain in many instances because of irritability

associated with inflammatory reaction which prevents adequate filling of the colon in the area of disease. This is sometimes compounded by difficulty in obtaining satisfactory preparatory cleansing of the bowel. In our first case, the diagnosis was made by following the barium through the small bowel into the colon, when it could not be made on barium enema examination.

Etiologic Speculations

The etiology is unknown. Much speculation without supportive evidence is found in the literature. Usual infectious organisms have not been found and there has been no histologic evidence of local vasculitis or generalized vascular disease in the patients reported. Our first case affords some interesting speculation as to a possible viral etiology. Among the cutaneous manifestations of incontinentia pigmenti which the first patient displayed were herpetiform ulcerations of the mouth, lips, and labia. Significantly, these also were of a chronic and recurrent nature. Geneticists would like to postulate a hereditary susceptibility to a *herpes-like virus* in this disease. The relationship of these external ulcers to those of the colon, while remote, makes a viral pathogenesis plausible. This nonspecific type of ulceration also appears to be distinct from the *stercoral** ulcer which occurs in elderly or debilitated patients secondary to adherent inspissated feces and found predominantly in the sigmoid colon.

While the *stercoral ulcer* is considered to be a different clinical entity, the mechanism of colonic stasis from any of a variety of causes is undoubtedly a contributing factor in some instances of nonspecific ulcer. Ulceration proximal to obstructing carcinoma has been noted by Glotzer et al.¹¹ who reported six cases. Multiple ulcers were present in all instances. Some of these had sharply margined ulcers with intervening mucosa intact, while others had involvement resembling idiopathic ulcerative colitis with pseudopolyps. These authors also demonstrated colonic ulceration and inflammation in dogs with experimental obstruction.

Severe nonspecific colitis and enterocolitis have been reported in patients with the functional obstruction found in *aganglionic megacolon* also. The cause is not known, although the ulcers in these cases are evidently related to obstruction.

Interference with mucosal blood supply has also been suggested as a possible cause. These lesions differ from the ulcers of ulcerative colitis in that there is less inflammatory reaction in the former. They differ from the simple ulcers described here in that multiplicity is the rule and inflammatory

Fig. 3-a — Barium enema shows pronounced deformity of the cecum. The remainder of the colon is normal.

Fig. 3-b — Compression spot film of the cecum shows the elongated irregular deep ulcer (long arrow) with the surrounding swollen mucosa and thickened bowel wall which resembles an intraluminal mass. The terminal ileum (short arrow) is slightly compressed but is not otherwise involved.

*See Test Your Word Score Page 1359.

reaction is minimal in these patients with megacolon.

The treatment is surgical excision. There is some difference of opinion as to the extent of excision, particularly in the lesions of the right colon. Surgical removal has generally been successful, but attempts at more conservative management have not. Cases in which long-term follow-up has been available following surgery have shown good recovery. Acute perforation requires emergency surgery with the type of surgery depending on the site of the lesion and the condition of the patient.

Summary

The roentgenographic findings in nonspecific

ulcer of the colon are similar to those of ulcers elsewhere in the gastrointestinal tract. Deformity caused by fibrosis may be extensive. In the chronic or recurrent ulcer, the diagnosis can be made on adequate barium studies of the colon with visualization of the crater. Complete recovery can be anticipated in a high percentage of patients following adequate surgical resection of the lesions. Two cases of nonspecific ulcer of the colon have been presented.

Acknowledgment

The authors would like to express their appreciation to Dr. Richard Schatzki, 1180 Beacon Street, Boston, Massachusetts, for his permission to use the roentgenograms in Case 2.

Gordeev's Fluid for Cancer

Some new preparations have been developed by Soviet scientists in the fight against cancer. The most common of these used for skin cancer is "Gordeev's Fluid," named after the scientist who discovered it. The liquid is injected by a specially constructed syringe into the substance of the cancer itself and around it, up to the border of the cancer tissue with the surrounding healthy cells. It produces an inflammatory process as a result of which the malignant elements of the cancer die and in its place is formed an ordinary scar.

The Leningrad oncologist, Professor Larinov, in collaboration with Professor Nemets, a chemist of the Leningrad Technological Institute, made a preparation they call "Embikhin," which contains the chemical compound, chlorethylamine. In many animal experiments Larinov gave this substance for treatment of serious cancer of the lymphatic system, and the results were good.*

Hemostasis and Thrombosis*

A
New
Look

ARMAND J. QUICK, Ph.D., M.D.**
Milwaukee, Wisconsin

NEAR THE END of his career, Papanicolaou remarked: "... while it may be a great personal satisfaction to make a discovery in the laboratory, we do not save lives in the laboratory. People's lives are saved where people are." Papanicolaou was aware that laboratories help save lives, but he wanted to point out that physicians actually treat the patient.

This is equally true of diagnosis. No matter how the laboratory helps to formulate the diagnosis, it is the patient's physician who makes and interprets the diagnosis and manages the patient. This is illustrated in two fields—hemostasis and thrombosis—both of which have been extensively studied by laboratory methods. Despite the time and effort expended in laboratories, hemostasis and thrombosis still present formidable problems.

The Cardiovascular System

To manage and control bleeding, one must understand the cardiovascular system. It has two important functional units: the heart and the microcirculation. In between are the relatively passive arterial and venous components.

Arterial and Venous Components

Loss of blood from a vein is rarely serious since the blood pressure is low. In the arteries the pressure is high, but the thick muscular walls protect patients from hemorrhage except when large arteries are severed. Then the hemostatic mechanism is inadequate, and the ligature becomes an indispensable stanching agent.

Microcirculation

The microcirculation is the Achilles heel of the vascular system. The arterioles are divested of much of their muscular protective coat and some are exposed; the capillaries can lose blood by leakage or diapedesis.† Clinicians were unable to

*Presented at the Symposium on Clinical Aspects of Hematology, St. Luke's Hospital, St. Paul, Minnesota, April 27, 1967.

approach the microcirculation and its hemostasis until Duke described the bleeding time in 1910. Here was a direct test on the patient without test tubes or other laboratory manipulations that required theorizing to explain. Duke established that the normal bleeding time was about three minutes and, significantly, that it was not prolonged in hemophilia.

Soon after, Minot and Lee and, independently, Von Willebrand discovered a disease in which the bleeding time was prolonged though the clotting time was not abnormal and the platelets were not reduced. Attempts to pinpoint a platelet or coagulation defect in patients with the disease gave equivocal results. But transfused plasma, even plasma from hemophiliacs, corrected the bleeding time. This indicated the lack of a plasma factor other than factor VIII.

Initial Step in Hemostasis

Effect of Acetylsalicylic Acid

Acetylsalicylic acid prolongs the bleeding time in many normal subjects and in patients with the Minot-Von Willebrand syndrome,* thus helping to formulate the first step in hemostasis (Figure 1). That sodium salicylate lacks this power to prolong the bleeding time gives a clue to how acetylsalicylic acid acts. Obviously, the acetyl linkage, not the salicylic acid, causes the prolonged bleeding time.

Under normal circumstances, a balance of two hormones of the autonomic nervous system, epinephrine—a vasopressor, and acetylcholine—a vasodilator, maintain the tone of the microcircula-

tion (Figure 1). After injury, cholinesterase is activated. Then it hydrolyzes acetylcholine, thereby destroying its vasodilating action. As a result, epinephrine dominates, vasoconstriction ensues, and the first step in hemostasis is completed.

Insufficient Cholinesterase

In a severe case of Minot-Von Willebrand syndrome, insufficient cholinesterase is generated after injury to hydrolyze acetylcholine. Patients bleed because vessels do not constrict initially. In mild or subclinical cases, enough cholinesterase is produced to give a normal bleeding time. But when patients ingest acetylsalicylic acid, the bleeding time becomes longer. The cholinesterase generated combines with the acetylsalicylic acid so that injury does not produce normal hydrolysis of acetylcholine.

While this explanation is theoretical, acetylsalicylic acid does prolong the bleeding time, and this action may be due to the failure of vessels to constrict. In the initial contractile phase, platelets accumulate and aggregate within the injured vessel, and then bring about the second phase of hemostasis. Through their content of serotonin, a vasoconstrictor, they supplement and prolong contraction. By aggregating, they may serve as a mechanical plug, but, more importantly, they liberate a clotting factor which interacts with factors VIII and IX, agents lacking in hemophilias A and B, to produce intrinsic thromboplastin. This substance initiates the clotting reaction which terminates by generating thrombin and forming a fibrin clot which seals the severed vessel and begins the reparative process.

A Three-Prong Mechanism

Hemostasis is essentially a three-phase mechanism, but each phase overlaps the other (Figure 2). They not only complement each other but actually compensate for one another. For instance, the Minot-Von Willebrand syndrome is a mild disorder because other coagulation mechanisms and platelets make up for its defect.

This protection against blood loss can be visualized as a three-line defense. Blood coagulation constitutes the third line of defense. Even with hemophilia, hemostasis is surprisingly good. Many hemophiliacs do not bleed from minor cuts, do not have nose bleeds, and do not experience gastrointestinal bleeding because the first line of defense, as measured by the bleeding time, is

*See Pages 1338 and 1423.

Fig. 1—Acetylsalicylic acid as a probable competitor of acetylcholine for cholinesterase.

Fig. 2 — The 3-line hemostatic defense.

normal.

Diagnosis of Hemorrhagic States

The three-phase scheme of hemostasis outlines the disorders and diagnostic tests for hemorrhagic states (Table). The bleeding time and the aspirin tolerance test, a bleeding time after a test dose of acetylsalicylic acid, identify the Minot-Von Willebrand syndrome. With the prothrombin consumption time, a platelet dysfunction can readily and reliably be established. In patients the qualitative platelet defect or thrombopathy is equally as important as thrombocytopenia. The one-stage prothrombin time and the prothrombin consumption time screen coagulation defects.

Fortunately, the wide use of the prothrombin time to control oral anticoagulant therapy has

made this procedure routine in most hospitals. The prothrombin consumption time is equally simple. A technologist who knows how to do the prothrombin time needs no additional training for this test. With minor modifications the prothrombin time and the prothrombin consumption time can sensitively detect nearly all coagulation defects.²

Common Types of Hemorrhage

Today those who write about hemostasis emphasize coagulation reactions and platelets. This is evidenced by a stream of papers on clotting factors, fibrinolysis, platelet stickiness, and platelet agglutination. Prosaic types of bleeding such as epistaxis, occult gastrointestinal bleeding, and menorrhagia receive scant attention. If the bleeding is sufficiently severe, patients may be sent to a specialist who handles the bleeding empirically.

Yet, these three types of hemorrhage outnumber all other forms of bleeding and bedevil the practicing physician. Each always has an underlying cause, and the physician's responsibility is to find it.

To do this, a medical history including hereditary background and a physical examination must precede the laboratory studies. The prothrombin time and the prothrombin consumption time will reliably screen coagulation and platelet defects. In most patients, neither a coagulation nor a platelet defect will be found. But since the Minot-Von Willebrand syndrome is the most common bleeding disease and is responsible for much mucous membrane bleeding, a surprisingly large number of cases will be detected by the aspirin

TABLE
A Diagnostic Guide to Hemostasis

DIAGNOSTIC TESTS	RESULTING HEREDITARY DISORDERS
Duke bleeding time	Minot-Von Willebrand syndrome
Aspirin tolerance test	
Prothrombin consumption time	Thrombocytopenias
Thromboplastin generation test	Thrombopathies

Clotting time	Afibrinogenemia
Prothrombin time	Hypoprothrombinemia
Prothrombin consumption time	Deficiency of factor V, VII, VIII, IX or X
Thromboplastin generation test	Hyperheparinemia

tolerance test.

The Minot-Von Willebrand syndrome, however, does not explain all mucous membrane bleeding. Epistaxis, for example, is more troublesome in hereditary telangiectasia.* Other disease can cause gastrointestinal bleeding, and the complex hormonal control of menstruation certainly does not permit singling out one cause to explain all cases of menorrhagia. Yet with the aspirin tolerance test as a screening procedure, Minot-Von Willebrand's disease can often be detected and the correctness of the conclusion verified clinically when patients stop bleeding after being off medications containing acetylsalicylic acid.

Multiple Hemostatic Defects

The first phase of hemostasis is vascular contraction. This is independent of both coagulation and platelets and is responsible for controlling the bleeding from small cuts and minor trauma. Often it is assumed that the bleeding in hemophilia is solely and directly dependent on the plasma concentration of factor VIII. However, I have had the opportunity to follow the clinical course of two hemophilic brothers, both of whom have a concentration of factor VIII of about 0.01 per cent of normal. Yet one of the brothers has required only two hospitalizations for bleeding and has no crippling joint deformities. His older brother has had numerous hospital admissions and is severely crippled. The first has a normal aspirin tolerance test while the second not only has a poor aspirin tolerance but has been a chronic user of this drug. These boys eloquently demonstrate that the severity of the bleeding tendency in hemophilia is not solely dependent on coagulation. By superimposing a faulty initial phase in hemostasis on a basic coagulation defect, the bleeding tendency is strikingly accentuated.

What is true of hemophilia should be equally applicable to other bleeding states. Today thousands of patients have coagulation depressed by oral anticoagulant drugs. Occasionally, serious hemorrhage occurs when the prothrombin time indicates a presumably therapeutic range. How many of such patients could be spared complications of this type by screening with the aspirin tolerance test and the judicious use of this drug, can only be surmised.

Thrombosis

Just as has hemostasis, so has thrombosis been

*See Test Your Word Score Page 1359.

dominated by thinking along the lines of platelet agglutination and hypercoagulability. Yet, in the slaying of the man who shovelled snow on a cold winter morning, it would be difficult for any scientific jury to find either the platelets or the coagulation mechanism guilty of having delivered the blow that stopped the heart. Arterial thrombosis presents a complex problem. Perhaps many of the atheromatous plaques represent scars of previous victories rather than punishment for having eaten Minnesota or Wisconsin butter. While platelets and coagulation do play a role in arterial thrombosis, it is equally certain that the autonomic nervous system with its own hormones along with various other hormones must be integrated to obtain a global concept.

Venous Thrombosis

Arterial thrombosis is too complex for this discussion, but venous thrombosis is not³ (Figure 3).

Fig. 3—The probable sequence in the formation of a venous thrombus. The initial injury of the vessel wall serves as the nidus by attracting platelets, with formation of a small clot which propagates by the extrusion of serum rich in thrombin. Sluggish circulation and anemia are controlling factors.

A slight injury to a vessel wall is probably common. Such an injury site attracts platelets which adhere to it, then enter into the clotting mechanism and assist in the generation of a little thrombin which clots enough fibrin to cover the affected area. Whatever excess thrombin is generated either becomes adsorbed to the fibrin matrix or is washed away by the bloodstream. Should the blood flow be sluggish, the local clot would enlarge and then on retraction extrude a serum rich in nascent thrombin. A secondary clot, attached to the primary one, then forms, repeating the cycle of retraction and extrusion of nascent thrombin.

Thus, from a small area on a vessel wall a thrombus can form and become large enough, when it is broken off by fibrinolysis, to produce a fatal pulmonary embolus. In such a concept, hypercoagulability can be dismissed; but hypo-coagulability as induced by anticoagulant drugs may counteract the thrombotic process. Anemia is dangerous because it brings about more rapid and complete clot retraction. On the troika of (1) improved venous circulation, (2) corrected anemia, and (3) effective anticoagulation, the journey towards prevention of venous thrombosis should be more successful.

Summary

Hemostasis is maintained by a three-line de-

fense:

1. Vascular contraction after injury brought about by the autonomic nervous system,
2. Platelets which supplement and complement the primary contraction and which initiate coagulation by supplying a factor essential for the intrinsic generation of thromboplastin, and
3. The coagulation mechanism which brings about the sealing of injured vessels and the beginning of the reparative process.

The important bleeding disease in which the defect is in the first phase is the Minot-Von Willebrand syndrome. The severity of a bleeding tendency is often a combination of defects in at least two components of the hemostatic mechanism.

Phlebothrombosis is dependent on an initial vascular wall injury which may actually be small and insignificant but still serve as the nidus for the growth of a large attached clot under the favorable conditions of sluggish circulation and anemia. This may eventuate in a massive pulmonary embolus. Hypercoagulability which is difficult to define or envision need not be postulated to explain a thrombotic proneness, but the induction of hypocoagulability by anticoagulant therapy has clinical support as a means of reducing venous thrombosis.

Frontier Granny Medicine

Sometimes young frontier doctors were given a few constructive suggestions from old grannies. These varied in their usefulness. Dr. Felix Collard, Wheelock, Texas, met an old lady riding down to the forks of Camp Creek.

"Be you a doctor?" she asked.

"Yes, I'm a practicing physician."

"Do you know a sure cure for pneumonia?"

"I fear I do not."

"Well, you are a young doctor, and I want to help you along and I want to give you a sure-shot cure for pneumonia. It's black cat tail tea. Find the blackest cat that you are able to find and cut off his tail and make a tea and mix it about half and half with good red liquor and have it hot. Give one tablespoonful every ten minutes until the patient goes to sleep. The only times I've known it to fail was when the cat wasn't black enough, the tail wasn't long enough or the patient didn't get the cure soon enough."*

Minnesota State Medical Association

Von Willebrand - Jürgens Syndrome

This has been classified as a constitutional, non-malignant, hereditary, hemorrhagic diathesis. Inheritance is as a simple mendelian dominant and numerous family members may be involved, usually in childhood.

Epistaxis occurs from nasal mucous membrane gingivae and from gastrointestinal or renal sources. There may be hemorrhages in the retina or in cutaneous tissue as petechiae with spontaneous ecchymosis. The platelet count is normal, but bleeding time is prolonged.*

MINNESOTA MEDICINE Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures highlighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Music and Disease

And it came to pass, when the evil spirit from God was upon Saul, that David took an harp, and played with his hand: so Saul was refreshed, and was well, and the evil spirit departed from him.

—I Samuel 17, 23.

Angiosarcoma of Lungs and Adrenal Gland

Unusual Clinical and Pathologic Manifestations

WILLIAM H. KERN, M.D.*
REGINALD H. SMART, M.D.*
RUSSELL P. SHERWIN, M.D.*
Los Angeles, California

MALIGNANT VASCULAR tumors are rare, and if they occur primarily in internal organs, the clinical diagnosis may present problems.^{1,6,9} Approximately two thirds of malignant vascular tumors are classified as Kaposi's sarcoma.² The great majority of patients with this disease have lesions on one or both lower extremities, but visceral lesions may be present,^{11,5,7,8} and occasional cases in which lesions histologically characteristic of Kaposi's sarcoma were limited to viscera have been recorded.^{1,5,8} The lungs are frequently involved by metastatic disease^{11,12,13} but primary involvement of the lungs by angiosarcoma or Kaposi's sarcoma is extremely rare.^{4,1} No reference could be found in the literature to primary involvement of the adrenal gland.¹⁶

The case presented is that of a patient who had an angiosarcoma involving his left adrenal and associated multifocal involvement of the lungs.

Case Report

The patient was a 57-year-old Jewish man with a two-month history of hemoptysis when first admitted to the hospital on September 23, 1965. Roentgenologic examination prior to admission had demonstrated a mass in the right upper lobe, and bronchoscopy showed bleeding from the right upper-lobe bronchus. After bronchoscopy the patient noted shortness of breath and a slight cough. The past history was unremarkable. He had smoked two packs of cigarettes daily until two years before. The physical examination at admission showed a blood pressure of 142/90. The hemoglobin measured 12.7 Gm. per 100 ml. of blood, with a leukocyte count of 8,100 per cubic millimeter and a normal differential count. On September 24, a right upper lobectomy was performed because of a presumptive diagnosis of bronchogenic carcinoma.

Operative Findings

The resected right upper lobe was pinkish-red, and the apical region and large portions of the posterior and anterior segments were atelectatic, hyperemic and hemorrhagic. There was no gross evidence of neoplasia, thrombi or emboli. Microscopic examination showed massive intra-alveolar hemorrhage and adjacent alveoli were found to contain a fibrinous exudate with associated active histiocytic and fibroblastic proliferation

*Departments of Pathology and Medicine, The Hospital of the Good Samaritan Medical Center and The University of Southern California School of Medicine.

Fig. 1—Organizing infarct in resected right upper lobe (X 250).

Fig. 2—Lung biopsy. Note alveolar spaces lined by neoplastic endothelial cells (X 250).

(Figure 1). Neoplasia or vascular proliferation was absent. Despite the absence of demonstrable vascular lesions, the intrapulmonary hemorrhage with localized organization was considered to represent infarction.

Postoperative Course

The postoperative course was uneventful and the patient was discharged on October 3. Serial A-P full-chest planograms revealed multiple nodules measuring 0.5 to 2.5 cm. distributed throughout both lungs, as well as bilateral mediastinal adenopathy. The findings were considered to be those of a disseminated hematogenous disease. Laboratory examination showed moderate anemia, with a hematocrit value of 29%, and a leukocyte count of 9,200; other tests were within normal limits. Biopsy of a left scalene lymph node failed to demonstrate significant abnormalities.

Subsequent Operative Findings

On October 18, a left thoracotomy was performed and several nodular lesions that measured from 2 to 20 mm. in diameter, located in various portions of the left lung, were biopsied. The tissue was yellowish to pink-red, nodular and moderately firm. Microscopically, there were multiple areas of necrosis and recent hemorrhage with focal organization and focal zones of greatly atypical cellular proliferation, occasionally with a papillary pattern. Some of these proliferating atypical cells were clearly alveolar in origin, but others could not be clearly identified as to type and site of origin (Figure 2). The findings were interpreted as a continuing process of

Fig. 3—Sputum showing single most atypical cluster in multiple specimens. Note histiocytes or neoplastic endothelial cells (X 850).

thromboembolism with pulmonary infarcts of varying age, inducing a very atypical bronchiolar hyperplasia suggesting the possibility of Kaposi's sarcoma.

Repeated cytologic examination of the sputum demonstrated only atypical histiocytes (Figure 3). Biopsy of a subcutaneous nodule in the neck on January 3, 1966, showed necrotizing inflammation and acute focal vasculitis, with occasional bizarre cells in necrotic areas similar to those observed in the lung biopsy.

After the thoracotomy, the patient grew progressively more weak and dyspneic. Values for hemoglobin and hematocrit remained low and he required repeated transfusions. Because of the possibility of pulmonary infarctions, as suggested at biopsy, the inferior vena cava had been ligated on October 22, 1965. At that time, all intestinal organs were normal to inspection and palpation, with the exception of the esophageal hiatus, which admitted three fingers. After the caval ligation, the legs became edematous. The patient continued to have hemoptysis, with fever up to 101°F. Because of the possibility of a collagen disease, such as Wegener's granulomatosis, he was given prednisolone and antibiotics. His condition continued to deteriorate and he died on January 6, 1966.

Autopsy Findings

The body showed no palpable peripheral lymphadenopathy or cutaneous lesions. Small, cystic, dark-red, nodular, hemorrhagic lesions averaging 5 mm. in diameter were noted in the anterior mediastinum, and larger confluent hemorrhagic nodules were seen in the parietal epicardium. The lung tissue was consolidated, dark reddish-pink, and contained yellowish to dark-red areas of old infarction, as well as several hemorrhagic nodules measuring up to 3 cm. in diameter. Most of these nodules were lobulated and located peripherally, with smaller hemorrhagic nodules in the pleura. Several peribronchial lymph nodes were enlarged to a diameter of 4 cm. and were soft, dark-red and hemorrhagic. Mediastinal lymph nodes showed similar changes. The gastrointestinal tract showed several small, raised, dark-red hemorrhagic mucosal nodules 5 mm. in diameter; one of these nodules was in the esophagus just above the cardia, four were in the stomach, and several were scattered throughout the mucosa of the jejunum. Similar 2 to 5 mm. hemorrhagic nodules were found in the subcapsular hepatic parenchyma, and a small nodule was present in the mucosa of the gallbladder. The right adrenal was of normal size and shape. The left adrenal was largely replaced by a mottled, yellowish to dark-red, hemorrhagic, soft, friable mass measuring 7.5 by 6 by 5 cm. In several places the thinned

Fig. 4—Lung at autopsy showing infarct-type necrosis with organization, resembling infarct in resected lobe (X 250).

Fig. 5—Direct smear of lung nodule at autopsy (Papaniicolaou stain X 850).

Fig. 6—Tumor in left adrenal showing spindle-cell (fibrosarcoma-like) component (X 500).

Fig. 7—Tumor in left adrenal gland demonstrating vascular spaces in cortex overlying main tumor (X 250).

adrenal cortex was stretched over this hemorrhagic tumor, which appeared to be of adrenal origin. A few small hemorrhagic nodules were also seen in the vertebrae.

Sections of the lungs showed multiple areas of consolidation and hemorrhage measuring from 0.8 to 3.5 cm. in diameter, located generally in the periphery. In the lower lobe of the left lung they were associated with acute necrotizing pneumonitis and severe polymorphonuclear leukocytic infiltration, whereas the lesions in the upper lobes were more hemorrhagic and resembled infarcts (Figure 4). Many of the alveolar septa either were necrotic, or were lined by cuboidal alveolar cells or neoplastic, apparently endothelial, cells. Smears showed the cytologic atypical proliferation to be considerably greater than that observed in the sputum (Figure 5).

In one area in the lower lobe, essentially normal alveolar lining could be traced, gradually changing to cells with larger nuclei that were elongated and resembled endothelial cells, and finally to a termination as a papillary club-shaped cluster formed and covered by neoplastic cells. The enlarged peribronchial lymph nodes showed extensive hemorrhage with a residual rim of lymphoid tissue measuring 2 mm. in thickness.

Fig. 8—Vascular subcapsular tumor in liver (X 40).

The mass in the left adrenal consisted mainly of proliferating, neoplastic, spindle-shaped cells with fairly large, generally elongated, hyperchromatic nuclei and a moderate amount of cytoplasm (Figure 6). Neoplastic vascular spaces were prominent (Figure 7). Residual adrenal cortex covered portions of the tumor, indicating direct involvement of the adrenal. The small nodules in the intestinal mucosa and liver demonstrated hemorrhage and proliferation of endothelial-like neoplastic cells partially forming vascular channels (Figure 8).

Comment

This case presents a number of unique and interesting pathologic features. It is debatable as to whether the lesion should be classified as a visceral form of Kaposi's sarcoma or as an angiosarcoma, presumably arising primarily in the left adrenal. Since the cutaneous lesions found in the vast majority of cases of Kaposi's sarcoma¹¹ were lacking and since histologically the tumor lacked the characteristic spindle-cell proliferation surrounding open vascular-like slits devoid of endothelial lining,⁵ a classification as angiosarcoma appears preferable. The fibrosarcoma-like spindle-cell proliferation seen mainly in the adrenal tumor may occur in angiosarcoma as well as in most other sarcomas.⁷ Primary angiosarcoma of the adrenal or predominant adrenal involvement in Kaposi's sarcoma has not been recorded in the literature.

The atypical proliferation of pulmonary alveolar cells is of special interest.^{14,15} These changes are particularly evident in infarcts or in pulmon-

ary fibrosis and may precede the development of adenocarcinoma of the lung.^{14,16} In our case there was pronounced and atypical alveolar-cell hyperplasia that was more prominent in the biopsy specimen than in the autopsy material, perhaps due to modification by treatment with corticosteroids. The alveolar-cell proliferation appeared to merge with and in a few areas could be traced to neoplastic proliferation of an angiosarcomatous rather than a carcinomatous lesion. The pattern suggested that the tumor in the lungs represented a multifocal process rather than a metastatic one and that the alveolar lining cells were undergoing in-situ malignant changes. A similar observation was made by Loring and Wolman¹ in their case of Kaposi's sarcoma of the lungs. They also noted the bizarre reaction of alveolar lining cells in contact with tumor, stating that the structural aberrations satisfied many of the histopathologic criteria for the diagnosis of malignancy. However, they thought that the absence of significant cellular proliferation or evidence of invasion suggested that the appearance of anaplasia was not associated with capability for autonomous growth.

Summary

The case of a 57-year-old man with angiosarcoma of the left adrenal and extensive metastatic or simultaneous multifocal involvement of the lungs is reported. Hemoptysis was the first symptom, and the original pathologic diagnosis was that of pulmonary infarction. The unique pathologic features and the changes in pulmonary alveolar cells associated with the neoplastic process are demonstrated.

No man has ever yet discovered the way to give friendly advice to any woman, not even to his own wife.—Balzac

Intensive Care Unit*

"I C U" said a nurse beside my bed.

Groggily, I thought she was playing "Peek-a-boo" with me and I replied, "I see you too, cutie." She had merely answered a question put to her by someone beyond my hearing. I was in the INTENSIVE CARE UNIT.

The last thing I remember prior to that was being laid out on a pad under a battery of light reflectors and being pleasantly told that I would be put to sleep.

What a vast difference there is in being anesthetized today compared with years ago in the days of chloroform and ether. I well remember the gagging sensation and the whirling brain that accompanied the first whiff of ether and the violent retching afterward.

From Wednesday through Saturday in the Intensive Care Unit I can recount little that is cogent. Much of the time must have been spent in the twilight zone, because the greater part of what I recall of those days and nights makes very little sense. I do remember the monotonous frequency of the thermometer, the blood pressure and pulse count around the clock; and I recall the angels of mercy with their hypods. At the least unusual sound two nurses were instantly at my side, where the head of my bed was equipped with every modern facility for saving life in an emergency.

Uppermost in my semi-comatose mind was that my surgeon and his consultants had emphasized that at all costs I had to cough—and cough some more. One strong young Nightingale invariably came and held me in her bear-hug, easing the pain immeasurably. She was warm and strong and fragrant, and she made this old man feel that he was important. I hated to be coughing almost directly in her face, but she said that it made no difference, that my cough was my own saving grace, as I had developed an atelectasis.

I made frequent trips in and out of the twilight zone during these five days and nights, and I talked audibly to people I have neither seen nor heard from in half a century and know not whether they are living or dead. At one point the Intensive Care Unit became a quonset hut in Achiet-le-Grande back in 1916 where the Canadian Corps on the Somme had its casualty clearing station and where a train-load of wounded soldiers had just been brought in. No life-saving

antibiotics in those days: either you had the Lord on your side or you passed in your checks: a dichotomy that made you a confirmed fatalist. Then back to reality and the unfinished job at hand—to cough, and cough some more.

When I was not sleeping, hour after hour was engrossed in watching the myriad holes in the acoustic ceiling tile as they transformed themselves into the most delicate gossamer lace, which constantly and gently rolled down in billowing folds until I could reach my hand up to penetrate its depths. I could not feel the lace; yet it was there. Was this, indeed, a shroud of the twilight zone stealthily seeking to envelop me on a trip to eternity? No, there were things left undone on earth—so cough, brother, cough. The coughing racked me with pain, but it set the ceiling back to normal so that the holes in the tile reappeared. But then I relapsed into my drugged and fevered semi-consciousness with the gossamer lace again re-forming and the cycle commencing all over again. I did not panic but simply waited until that shroud had almost reenveloped me before I beat the powers of fate by again coughing.

On several occasions the seemingly inexorable approach of the lace curtain was attacked by a force of millions of little black bugs that darted in and out as if attempting to repulse it. The lace and the bugs see-sawed back and forth for supremacy—the lace eventually winning out and swallowing up its attackers as it continued its relentless urge of smothering me in its folds. Needless to say how pleased I was on the first day out of Intensive Care when I had full control of all my senses and could receive visitors!

I shall always sing hymns of praise for the unselfish dedication of the Nursing Staff of the St. Barnabas Hospital Intensive Care Unit, not only for the attention that they paid to me, but that which was given to the others in the Unit. The nurses are all, indeed, true Florence Nightingales and have a right to be proud of their profession.

I do not wish to imply that no credit is due to my surgeon and his consultant and all of the others who helped in my recovery, for it is their knowledge and experience and dexterity that have made an Intensive Care Unit an efficient and invaluable adjunct of a modern hospital.

*Excerpts from a letter.

Diabetes, Peptic Ulcers, and the Hypothalamus

ROBERT E. BUCKLEY, M.D.
San Francisco, California

IT HAS LONG been known by clinicians that there is an apparent protection against the development of peptic ulcers among patients who have diabetes. The incidence of peptic ulcers among diabetics is about one fourth that of the general population. In 1940 Wilder reported that 3.5 per cent of the general population develop ulcers, but only 0.77 per cent of diabetic patients do. No cases of peptic ulcer were reported in a group of 4,103 diabetic patients before insulin.¹ One of the important effects of the treatment of peptic ulcers with the Sippy diet is that the frequent feedings induce a consistent hyperglycemia.

Hypoglycemia

There is an increased occurrence of hypoglycemic reactions among patients who have peptic ulcers. Berry found that seven of 10 of his ulcer patients had functional hyperinsulinism during their five-hour glucose tolerance test when the test was taken without dietary preparation.² None of his 10 control patients developed hypoglycemia. Abrahamson found that all members of a group of twenty-seven ulcer patients developed hypoglycemia.³ Hypoglycemia has been found to increase the gastric acidity, cause hypersecretion, increase peristalsis, and induce hypertonus.² Studies of the effect of hypoglycemia on experimental animals confirm these clinical findings. Poth and From reported that 50 per cent of dogs sustained in hypoglycemia would develop ulcers.⁴ The studies by Hans Selye on the gastrointestinal tract responses in the alarm reaction are quite pertinent here. In 1936 he reported that insulin overdosage, like other procedures which cause hypoglycemia—such as adrenalectomy, fasting, and partial hepatectomy, will increase the incidence of ulceration when other stresses are applied to rats.⁵ He reported a further study in 1944 which has even more importance to the study of the relationship of blood sugar and peptic ulceration. He found that various foods, and particularly dextrose, were effective in protecting animals from ulcers,⁶ and that dextrose gave protection when given by gastric lavage and also when given parenterally. In this study, the stresses which

were applied to the rats, such as pain, cold, and transection of the spinal cord, did not induce hypoglycemia. The implication of this study by Selye is that hyperglycemia has a protecting effect over and above that of merely preventing hypoglycemia.

The biologic basis of these findings will be found in the more recent work which has been done on the neurophysiology of the hypothalamus. Two study groups have focused attention on the hypothalamus: the neurophysiologists concerned with the central nervous system's influence on the gastrointestinal tract,⁷ and the nutrition groups concerned with appetite and the gluco-receptor centers within the hypothalamus. When the work of these investigators is combined, the biologic basis for these observations is clarified.

The groups which are concerned with the influence of the central nervous system on gastrointestinal tract activity usually separate the hypothalamus into the anterior and posterior sections. The anterior area has been described as having a rather basic association with the parasympathetic division of the autonomic system. Stimulation in the anterior area is associated with increased activity of the gastrointestinal tract, including increased secretion of hydrochloric acid. These effects are mediated by way of the vagus nerve.⁸ Stimulation here has also caused thickening of the gastric mucosa, with changes in its

cell types and distribution which are consistent with the increased gastric acidity and the peptic ulcers which develop.⁹ Destructive lesions in the posterior portions of the hypothalamus have been reported to have similar effects of inducing both gastric hemorrhages and ulcers. The similarity of results of anterior stimulation and posterior destruction are believed to result from the over-activity of the anterior portions occurring in both instances. The anterior hypothalamus can become more active when deprived of its interaction with the posterior region which is necessary for over-all balance of function.

There has also been some similarity of results when destructive lesions of the anterior regions are compared with stimulation in the posterior regions. These experiments have caused the development of hemorrhages, and perhaps gastromalacia, but have not been associated with the development of peptic ulcers.¹⁰

One problem of these experiments needs to be considered here. There is no clearly demarked or definable line of separation of the anterior and posterior areas. The conclusions of Long in 1962 was that it is most important to get electrode placement in "a low, mid-line position" in order to cause the non-specific autonomic dysfunction which he felt was basic for disturbance of function of the gastrointestinal tract.¹¹ This study cautions that we should not attempt to be too precise or rigid in our designation of anterior or posterior areas; it emphasizes that the consistent responses which have been obtained by many different investigators have come from the areas which border upon the lower part of the third ventricle.

The nutrition groups have focused their attention on the medial and lateral hypothalamic areas. The medial area, containing the ventromedial nucleus, functions as a "satiety area" to inhibit activity in the "feeding area" of the lateral hypothalamus.¹² The medial satiety area has been found to be sensitive to the level of circulating glucose. Elevations of blood sugar will cause the satiety area to inhibit the lateral "feeding area." Destruction of the ventromedial nucleus will prevent it from inhibiting the feeding area which then becomes overactive. Such animals develop hyperphagia and become obese. Destruction of this lateral "feeding area" causes such food avoidance that the animals may starve themselves if not force-fed.

Fig. 1—This section of the brain illustrates the site of the hypothalamus, and indicates the location of the cross-section of the hypothalamus.

Gluco-Receptor Area

It is the presence and location of the gluco-receptor area which is of importance for the topic of peptic ulcers and diabetes. Changes in the levels of activity of these areas have been demonstrated to be associated with the levels of blood glucose.¹³ Another type of demonstration of the locus of sensitivity to sugar has been the destruction of certain areas here by gold thioglucose. When this chemical is given to rats at the LD-50 dosage level, 60 per cent of the survivors will have a pattern of overeating and obesity which is similar to that of animals with stereotaxic lesions of the ventromedial hypothalamic nucleus. The microscopic examination of their brain reveals destruction of neurons of the arcuate or periventricular nucleus, the ventromedial nucleus and occasionally the supraoptic nucleus. These lesions occur only if glucose is part of the molecule, since similar compounds, such as gold thio-glycerol or gold thiomalate, have comparable toxicity yet do not give localized injury here. These chemical lesions help us to identify the glucose-sensitive areas of the brain more precisely, and they are found to be in the low mid-line areas, bordering on the lower part of the third ventricle.

The influence of diabetes on gastrointestinal tract activity appears to be a function of the blood sugar level rather than the overall metabolic effect of diabetes. This seems confirmed by the findings that glucagon will induce elevations of blood sugar and a reduction in gastric activity. Melrose found that glucagon will inhibit spontaneous secretion of gastric acids, and yet will not inhibit the acid output obtained in a "maximum" histamine response.¹⁶ This suggests that the effect of the glucagon hyperglycemia is not peripheral, at the level of the gastric mucosa, but is central. Mayer has reported that the central effect of hyperglycemia is on the gluco-receptor area. He found that glucagon hyperglycemia does inhibit the gastric contractions of normal rats, but does not inhibit the gastrointestinal motility of rats which have received damage to their ventromedial nucleus.¹⁵ This study provides confirmation that elevation of blood sugar can have a direct effect on the activity of the gastrointestinal tract, and that this change in activity requires that the gluco-receptor area remain intact.

Integration of Observations

When we integrate the overlapping areas of study of these two groups, we find a useful proposition for the biologic basis of the protection which diabetic patients have against peptic ulcers. The hypothalamus must remain intact in order to continue its normal and integrated activity. The effect of destructive lesions will be to interfere with the balance of activity of the hypothalamus as a whole. When an inhibiting area is destroyed, the effect will appear as if stimulation had occurred, since the activity of the hypothalamus will continue without the negative feedback from the destroyed area. There can be similar paradoxical results when stimulation is applied to such an area. The effect of stimulation of an inhibitory area will be to diminish the hypothalamic activity. This has been found to be the case with respect to the activity of the ventromedial nucleus of the hypothalamus. Destruction of it causes increased activity of the feeding center, and the animal becomes hyperphagic. Stimulation of it will inhibit activity in the lateral hypo-

Fig. 2—This illustration of the hypothalamus indicates the location of the ventromedial and arcuate nuclei which are cross-hatched. The arrows indicate negative feed-back circuits which are activated by hyperglycemia, and inhibited by hypoglycemia.

thalamus.¹³ This nucleus has been found to be part of the gluco-receptor area; it can be stimulated by elevation of the blood sugar level, inhibited by hypoglycemia. It is proposed that the inhibitory effect which follows elevation of blood sugar is not limited to the lateral hypothalamic feeding area but also includes the adjacent anterior hypothalamic area which is involved with the development of peptic ulcers.⁹ Elevations of blood sugar have been found to inhibit gastrointestinal tract activity,¹⁵ and to protect animals from development of ulcers during the alarm reaction.⁶ The blood sugar level is one of several factors which affect the function of the gastrointestinal tract. This information provides us with a basic foundation for increasing our understanding of the biologic basis for the protection which diabetes provides against the development of peptic ulcers.

Summary

The gluco-receptor mechanism has been found to be associated with the centromedial and arcuate nuclei of the hypothalamus. Activation of this mechanism by elevations of the blood sugar has been demonstrated to inhibit the feeding center of the lateral hypothalamus. It is proposed that activation of the gluco-receptor mechanism to inhibit the function of an adjacent nucleus is not limited to just the lateral hypothalamus. This inhibition will include the anterior and posterior hypothalamic areas as well.

mic areas as well.

Activation of the anterior hypothalamus is associated with the experimental production of peptic ulcers. If we accept the proposition of this paper, we must conclude that the activation of the gluco-receptor mechanism by hyperglycemia will cause an inhibition of the anterior area and protect against peptic ulcers. It has been clinically observed that diabetes protects against peptic ulcers, and that dextrose protects experimental animals against ulcers. These findings tend to support the proposition.

The findings relative to hypoglycemia provide us with further confirmation. Chronic hypoglycemia has been found to be a factor in the experimental production of ulcers, and the flat glucose tolerance curve which results in hypoglycemia has been repeatedly found in patients with peptic ulcers. The effect of hypoglycemia will be to diminish the activity of the ventromedial nucleus. When the activity of this negative feed-back inhibitory circuit has been diminished, adjacent areas will be released, and will tend to behave as they do when stimulated.

The blockade of an inhibitory circuit releases the "target area" to perform its inherent physiologic activity. When the anterior hypothalamus is activated, this parasympathetic center will act by the initiation of the cephalic phase of digestion if the vagus nerve is intact. The animal will then be prone to the development of peptic ulcers.

If, in a woman pregnant with twins, either of her breasts loses its fullness, she will part with one of her children; and if it be the right breast which becomes slender, it will be the male child, or if the left, the female.—Hippocrates

YOUR HEALTH! MR. PRESIDENT

William McKinley (1843-1901)

Hostages to fortune, Bacon called us all; but our Presidents suffer double exposure to the proverbial "slings and arrows." In the case of four of our Presidents the agent of "outrageous fortune" was a bullet.

William McKinley was our twenty-fourth President, the fifth to succumb in office and the third of four to die by assassination. As a lad he was just a normal, healthy American boy: one single component of that anonymous reservoir from which our national public figures are destined to emerge. Sportswise he was proficient at marbles, adept at bow-and-arrow marksmanship, and avidly addicted to swimming.

Later at college, young seventeen-year-old William suffered a general physical collapse, from which indeterminate and non-specific malady he must duly have recovered, for at eighteen he joined the Ohio Volunteers to fight in the Civil War. Throughout his military service he appeared to have a charmed life: impervious to enemy fire and immune to camp fever. Further, as a bonus, he was awarded official recognition for heroism on the battlefield.

In manhood McKinley was a strikingly handsome and healthy specimen, with no other disability than a "tobacco heart." Cigars were his one and only indulgence; but he was meticulously careful never to be photographed with them in evidence. Alcohol he never touched.

On September 6, 1901, while standing in a receiving line at the Pan American Exposition in Buffalo, New York, McKinley was fired upon at close range by one Leon Czolgosz as the two men were apparently about to shake hands. Two shots hit the President: one bullet flesh-grazing his chest and later dropping from his clothing; the other bullet entering his body above the navel. Surgical exploration through a five-inch incision showed that the bullet had passed through the stomach, leaving a small smooth aperture where it entered and a large rough one where it exited—to lodge irretrievably somewhere in the back. Both stomach holes were carefully sutured, special care being taken that no stomach contents escape into the abdomen to cause peritonitis, the one complication the doctors dreaded most. The critical surgery lasted one hour and was performed with the only instruments at hand, those from a pocket case, the grim scene illuminated by the waning daylight intensified by and reflected from hand mirrors. The bullet was not recovered.

Late that night an official bulletin announced to the shocked and shaken nation: "The President is rallying satisfactorily and is resting comfortably. Temperature, 100.4; pulse, 124; respiration, 24." Early the following day the anxious country heard the optimistic report: "The President continues to rest well. Temperature, 101.6; pulse, 110; respiration, 24"; and on Monday, September 9 the reassuring: "The President's condition steadily improves and he is comfortable, without pain or unfavorable symptoms. Bowel and kidney functions normally performed."

By Wednesday McKinley had so markedly improved that he could eat. He even requested a cigar, which naturally was denied him.

But on Thursday the tide turned. Optimism yielded to pessimism as the President's condition began to deteriorate rapidly, a bulletin on Friday announcing: "The President is suffering from extreme prostration. Oxygen is being given. He responds to stimulation but poorly. Pulse, 125; respiration, 40." The end came early the following morning.

A touching note is poignantly recalled by the writer of this monograph: McKinley's request as the final shadows deepened, that the window shade in his room be

Continued

raised to admit more light. Incidentally, his favorite hymn was Lead, Kindly Light.

The autopsy report, signed by two U. S. Army surgeons and eleven other attending doctors, stated:

"The bullet which struck over the sternum did not pass through the skin and did little harm. The other bullet passed through both walls of the stomach near the lower border. Both holes were found closed by the stitches, but the tissue around each hole was gangrenous. After passing through the stomach, the bullet passed into the back walls of the abdomen, hitting and tearing the upper end of the left kidney. This portion of the bullet track was also gangrenous, the gangrene involving the pancreas. The bullet was not found. There was no sign of peritonitis or disease of other organs. The heart walls were very thin. There was no evidence of any attempt at repair on the part of nature, and death resulted from the gangrene which affected the stomach around the bullet wounds as well as the tissue around the further course of the bullet."

With acknowledgments to Karl C. Wold, M.D.: Mr. President—How Is Your Health? 1948.

What's New!

Parke, Davis & Company announced recently that it had added three new sizes of Redi-Wrap Gauze Sponges, Sterile to its expanding line of medical-surgical products.

The new sizes of gauze sponges are put in Sponge-Control Envelopes, each containing two sponges.

Each package of Redi-Wrap Gauze Sponges is code-colored red, is tamperproof to assure sterility, and features ready-to-use convenience.

UNIMATIC packaging of tablets and capsules is now available from E. R. Squibb & Sons, Inc.

The importance of drug distribution systems in the UNIMATIC package is a means of providing a more efficient, better control over drugs. The new UNIMATIC tablet and capsule form will be supplied in strips of ten, with ten strips per compact box.

Squibb also markets a unit-dose disposable syringe under the UNIMATIC trade name.

TALWIN (pentazocine), a non-narcotic analgesic, has been approved by the FDA. This drug has been effective in doses of 30 milligrams given by injection, approximating the effectiveness of ten milligrams of morphine. Testing in the United States over the past nine years has indicated the drug to be well tolerated with a low incidence of side effects. Mild sedation has accompanied the pain relief in many instances. Tolerance and addiction are not reported and because the new preparation is not a narcotic, it has the additional advantage of being dispensable without inventory control. (Winthrop Laboratories)

Fractures of the Mandible*

THIS DIAGNOSIS and treatment of mandibular fractures may appear, at first, to be simple and uncomplicated. The cardinal objective in treatment is the restoration of function performed by the dental and supporting structures of the dental complex. The technical procedures by which this objective may be accomplished are numerous. Two fundamental factors, however, are necessary for successful treatment: proper reduction and adequate immobilization.

No one method of treatment will give proper reduction and adequate immobilization in every patient. The age and health of the patient may perceptibly influence the treatment plan; correspondingly, the ability and experience of the surgeon may bias the selection of a certain technical procedure. Finally, the circumstances under which the patient is treated may render selection of one method over that of another more advisable.

Historically, the cliché, "The simplest is the best," has been considered to be synonymous with competent treatment of mandibular fractures. Although this cannot be challenged in principle, in reality the simplest treatment may be undertreatment; and undertreatment is often appended by postoperative problems. For example, closed reduction of mandibular symphyseal fractures is simple, but unfortunately this method often allows the segments at the inferior border of the mandible to spread. At best, malunion may occur, and the possibility of nonunion

is recognized. Adequate immobilization of these fractures may often be accomplished by means of a trans-osseous wire placed below the apices of the teeth. This may be performed intra-orally, thus eliminating the necessity of an extra-oral incision.

Extra-oral skeletal pinning is not as obsolete as some authors have indicated. There are selected fractures in which this procedure is an excellent modality of treatment, and the knowledge and ability to utilize this technique should perhaps be mastered by anyone who treats facial trauma. The older appliances were definitely

Use of quick-curing acrylic for stabilization of pins.

Eczema of many years... controlled in two weeks

Before treatment

After treatment —
with ARISTOCORT Topical
Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side

effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive non-permeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyodermas will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Available in 5 Gm. and 15 Gm. tubes and ½ lb. jars.

cumbersome to the patient and too expensive for the surgeon to place indiscriminately. However, the biphasic pinning technique incorporates quick-curing acrylic plastic for stabilization of the pins (Figure); this makes possible lighter appliances, more comfort for the patient, and less investment in equipment. In addition, this technique allows the continued use of the mandible, thus eliminating the need for intermaxillary fixation.

Decisions regarding teeth that are in the line of a mandibular fracture are often difficult. If the fracture occurs at the angle of the mandible and transverses an impacted third molar, it is frequently advisable to remove the impacted tooth and, at the same time, set an intra-osseous wire (intra-orally) in place. There are certainly some indications for retaining an impacted tooth, for example, when the tooth prevents displacement of the proximal segment. In this situation the patient should be given antibiotic coverage until good healing has been observed. This period of antibiotic coverage may well correspond to the period of immobilization.

Recommendations regarding length of immobilization of the fractured mandible vary among traumatologists. Although six weeks is an average length of immobilization, it is not the maximal period that can be tolerated physiologically. Certainly the type of fracture, associated medical problems, and the age of the patient all serve as guidelines for decisions regarding length of

immobilization. Often it may be advantageous to leave the arch bar or mandibular splint attached to the teeth for a week (or longer) immediately after removal of intermaxillary fixation. This allows for observation during the initial period of returning function of the mandible.

My final thoughts concern mandibular fractures of children. Fortunately, such fractures are infrequent. As is true for older patients, individual circumstances dictate the most advisable treatment plan. It has been found efficacious, however, to utilize an appropriate stock bite index. The unique occlusion of the patient is determined and maintained by means of an impression compound or a quick-curing acrylic. The mandibular occlusal index is then stabilized with circummandibular wires. This procedure, when indicated, has obvious advantages and is well tolerated by pediatric patients.

In the final analysis, there is a myriad of variations of technical procedures for treatment of mandibular fractures. The successful treatment encompasses those techniques that will ultimately restore occlusion and function of the masticatory apparatus. The key to successful treatment revolves around the surgeon's knowledge of the occlusion of his patient, whether the dentition is deciduous, mixed, or permanent.

Gastrocamera

DR. BARTNESS* reports on the radiological accuracy of distinguishing benign and malignant gastric ulcers. He reported 98 per cent accuracy, in a series of 150 gastric ulcers, in differentiating benign from malignant ulcers solely by radiological techniques. This result is at variance with that reported by others.^{2,3,5} The discrepancy may be explained on the basis of the more advanced radiological equipment and techniques used by Bartness. However, only four of the ulcers were malignant in his series. If all the ulcers were diagnosed as benign the accuracy would still be 97 per cent. Of the seven gastric ulcers that were diagnosed as malignant radiologically, only four were proven to be histologically malignant.

In the last few years there has been a resur-

gence of interest in gastroscopy and intragastric photography. Although high quality photographs had been made through the standard gastroscopy, the procedure was cumbersome and not readily applicable to routine use. The first practical gastrocamera was developed in Japan in 1950 by Drs. Uji and Hayashida of the University of Tokyo and the Olympus Optical Company of Tokyo. The first extensive clinical evaluation began in the United States in 1962 by Morrissey and co-workers¹ at the University of Wisconsin. They used the Olympus Gastrocamera Model GT V which was lowered into the stomach, and blind photographs were taken from several different positions. The camera is located in the distal end of the tube which has a removable tip for insertion of the film cassette. Thirty-two individual colored pictures can be obtained from a

*"When I couldn't even smell corned beef and cabbage,
I decided it was time for you, Doc."*

Maybe he doesn't know when he's well off. But you might want to prescribe long-acting Novahistine LP anyway.

Two tablets in the morning and two in the evening will usually provide day and night relief by helping to clear congested air passages for normal, free breathing. Novahistine LP is formulated to provide continuous therapeutic effect for 8 to 12 hours. The decongestant ingredients help restore normal mucus secretion and ciliary activity—physiologic defenses against infection of the respiratory tract.

Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result. Each Novahistine LP tablet contains: phenylephrine hydrochloride, 25 mg., and chlorpheniramine maleate, 4 mg.

NOVAHISTINE® LP

PITMAN-MOORE Division of The Dow Chemical Company, Indianapolis

5 mm. film cassette. A small flash lamp is housed in the camera beyond the lens and can be activated by the examiner. There is a flexible joint above the camera which permits the camera unit to be tilted up or down 35 degrees from a horizontal plane. The latest version is the Olympus Model GTF which contains an image-carrying bundle of fiberglass and an objective lens which covers approximately the same field as the gastrocamera lens. This instrument therefore allows gastroscopic examination and intragastric photography simultaneously.

In contrast to conventional gastroscopy, the procedure is not difficult and produces a minimum of patient discomfort, as the gastrocamera tube is soft and flexible. It can also be used repeatedly in the same patient.

In a series of 62 benign gastric ulcers, Morrissey et al.,² using the Olympus GT V gastrocamera, gastroscopy and X ray, found 66 per cent diagnosed by X ray, 58 per cent by gastroscopy, and 74 per cent by gastrocamera. The addition of the gastrocamera to X-ray studies increased the accuracy to 95 per cent. Hara et al.,³ in a study of 1100 patients with some gastroenterological complaints, found gastric ulcers in 204 and gastric cancer in 107. In the ulcer group, the X ray and gastrocamera were each positive in 60.5 per cent; 12.8 per cent were negative by X-ray examination but found by the gastrocamera. Most of

the latter group were small, shallow ulcers. In the group of 107 gastric carcinomas, positive results by both X ray and gastrocamera were found in 86 per cent. The gastrocamera failed in 6.5 per cent while the failure rate was 7.4 per cent by X ray. Chrysospathis⁴ reported the correct diagnosis in 121 of 126 benign gastric ulcers and 66 of 71 gastric carcinomas using the gastrocamera. From Australia, Milton, Lynch and Skyring⁵ reported 250 cases of gastric pathology and obtained a high percentage of accuracy with the gastrocamera, especially in diseases of the antrum and the lesser curvature. The gastrocamera has also been useful in the diagnosis of gastritis and gastric atrophy and in the detection of other forms of gastric pathology such as benign and malignant polyps, leiomyomas and phytobezoars.*

Although there is much to support the value of the Olympus Gastrocamera GT V as a blind procedure, the development of the Olympus GTF Gastrocamera, which permits gastroscopic examination and simultaneous intragastric photography, provides additional accuracy in the diagnosis of gastric lesions.

Gastroscopy and gastrocamera studies are not intended to replace radiological examination; indeed they are ideally complementary and will provide a higher degree of diagnostic accuracy of gastric pathology.

Oral Contraceptives

STEROIDS ARE currently being taken orally for contraceptive purposes by six or more million women in the United States. Repeated studies with each of the compounds leave no doubt about their contraceptive efficacy.

Considering that the prototypes of the two active ingredients in the oral contraceptive medications are estrogen and progesterone and that

the production of these two hormones increases during pregnancy, one might expect the medications to produce the physical symptoms and the changes in organ function which one would normally associate with pregnancy.

Initial concern about the safety of these agents was directed to their effects on blood coagulability. It is generally agreed that with the use of these

Continued

Mike expects a penicillin injection. He's about to be pleasantly surprised.

His physician is going to prescribe an oral penicillin —PEN·VEE® K (potassium phenoxymethyl penicillin). It's usually so rapidly and completely absorbed that therapeutic serum levels are produced in 15 to 30 minutes. Higher serum levels generally last longer than with oral penicillin G.

Indications: Infections susceptible to oral penicillin G; prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.

Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.

Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.

Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.

Adverse Reactions (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").

Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

ORAL **PEN·VEE® K**
(potassium phenoxymethyl penicillin)

medications there is an increase in factor VII level. Increases in levels of factors VIII and X and fibrinogen have been reported to occur sporadically. Studies of hepatic function have shown inconsistent increases in serum bilirubin, alkaline phosphatase, glutamic-oxaloacetic transaminase and glutamic-pyruvic transaminase, and impaired excretory capacity for sulfobromophthalein. Thyroid function studies have shown increased levels of protein-bound iodine, butanol-extractable iodine, and thyroxine-binding globulin, and a decrease in erythrocyte triiodothyronine-binding coefficient. There has also been reported increased secretion of aldosterone and increased plasma cortisol levels.

Dr. Spellacy* has previously demonstrated that women taking large doses of norethynodrel with mestranol (Enovid) have increased fasting blood sugar and plasma insulin levels. Now he and his

*Spellacy, W. N., Birk, S. A., Noer, K. A., and Schade, S. L.: Sedimentation Rate in the Normal Menstrual Cycle or with Oral Contraceptive. *Minnesota Med* 50:645, 1967.

co-workers have shown that these medications can cause an increase in the average erythrocyte sedimentation rate, although the range of values remains essentially the same as in nonusers.

The significance of the problem potentially inherent in the use of oral contraceptives seems to lie in (1) whether or not persistence of these changes for long periods is harmful and (2) whether or not these changes would persist after cessation of use of the compounds.

The above changes are reported to occur less constantly and to a lesser degree than in pregnancy. Because there is currently no evidence that these changes are harmful or persist after cessation of use of the compounds, after short or prolonged use, the major consideration at the present seems to be an awareness of the effect of these drugs on the various laboratory studies and a cautious interpretation of the results when the patient being studied is taking oral contraceptive medication.

Non-Symptoms

A SYMPTOM can be defined for medical purposes as the subjective evidence of illness.* It is a useful word denoting that portion of disease which disturbs the patient. Throughout history physicians have studied the symptoms of disease and given utmost consideration to their description by the patient. Their presence often dictates the treatment, and absence of symptoms may be the decisive influence against therapy. In the field of symptomatology there is another useful concept not well defined in medicine which can be labeled the non-symptoms. These are the evidences of disease which usually are the cause of the patient's complaint but for various reasons are ignored, suppressed, or otherwise not recognized. Meador's discussion on non-disease¹ stimulated this essay on non-symptoms. Although non-disease implies no disease, non-symptoms, on the other hand, cannot be equated with no disease.

A 67-year-old man complained of recurrent episodes of syncope. He denied dyspnea or an-

gina. No disturbance in mood was detectable. The pulse rate was 28-30 per minute. An electrocardiogram showed an atrial rate of 60 with a variable 2:1 and complete A-V block with ventricular rate as above. A transvenous pacemaker was implanted in the right infraclavicular space, threaded into the right ventricle, and set to drive the heart at 70 beats per minute. The next day the pulse was 70 and regular, and a remarkable improvement was evident. The patient was euphoric, stating he was no longer depressed. Shortness of breath and a feeling of constant pressure in the chest were gone. When asked why he had not previously mentioned his mental depression, chest pain, and angina, he stated that he was much more aware of these symptoms after their sudden subsidence. However, he now had a new and original complaint. The site of the batteries would interfere with the seating of his rifle and might spoil deer hunting in the fall. This non-symptom is of social rather than medical importance.

Non-symptoms pervade every field of medicine. The child with a congenital disorder recognizes his symptoms only upon relief. The victim of

Continued

*The definition of symptom in Merriam-Webster 2nd Edition and in Dorland's 24th Edition does not differentiate between symptom and sign. Current medical usage, however, favors the use of sign for an objective finding and symptom for a subjective complaint.

What can be done for Susan Jane To stop the runs and crampy pain?

Parepectolin for quick relief of acute diarrhea
...soothes colicky pain with paregoric
...consolidates fluid stools with pectin
...adsorbs irritants with kaolin, and protects
intestinal mucosa.

In children, Parepectolin may be used to control
diarrhea promptly and prevent dehydration,
until etiology has been determined. In some
cases, Parepectolin may be all the therapy
necessary.

insidious disease may complain very little, not recognizing imperceptible changes. Thus a patient with mitral disease may describe weakness and inability to climb stairs only after the valve has been corrected. The non-symptoms are then recognized as real symptoms.

Dissimulation leads to another form of non-symptom. An example is the absence of angina pectoris among licensed pilots. These men may have myocardial infarction, but angina of effort in flying personnel is a curiosity. Perhaps the loss of the license to fly, attendant upon the disclosure of the symptom, is a factor in producing a non-symptom.

Fear can suppress symptoms. Many patients visit their physician to be reassured that they are free of disease. Like a school boy mouthing an

answer to please the teacher and get a good grade, the patient may give the "right" answers that give him the "A" in health he fervently seeks. A 60-year-old man came to the doctor's office for a routine physical examination. He denied all symptoms. He submitted to an examination but refused a rectal examination. The persistent physician finally obtained consent for this procedure. As the patient dropped his shorts he volunteered the information: "You know, doctor, I've had a little bleeding down there the last few months." Fortunately his rectal cancer was resectable. The physician alert to the non-symptoms realizes there is no routine physical examination. There is only the failure to discover the complaint.

You May Be Right

In an editorial, entitled "An Obstetrician Proposes a Change in the Abortion Laws," MINNESOTA MEDICINE, May 1967*, the writer states that "therapeutic abortion is not needed as a solution to the problem of pregnancies resulting from rape" and says further that "we as physicians are now able to effectively prevent pregnancies up to 48 hours after intercourse by the use of an estrogenic substance." He draws this conclusion from a paper by Morris published in the American Journal of Obstetrics and Gynecology, 96:804, 1966.

I would like to take issue with this point of view on two grounds. A careful reading of the original paper by Morris leaves much doubt as to the efficacy of this type of "medical abortion" and, secondly, evidence from a Professor of Law at the University of Minnesota indicates that if physicians in this state use such means to prevent pregnancies resulting from rape, they may be risking up to four years of imprisonment, if convicted, under the present statute dealing with abortion in Minnesota.

In the original paper by Morris, he states that certain rape cases were given 50 mg. of stilbesterol for four to six days after exposure and that "in this *small* series of cases no patient has become pregnant so far." He further says that the side effects of this dosage of oral estrogen were undesirable because of nausea and mastodynia. He comments: "In these *preliminary* trials there have been no pregnancies. These clinical studies are *incomplete* and have as yet *no* statistical significance." He then continues: "These agents *may* inhibit implantation of the fertilized ovum. Because there may be undesirable side effects of estrogens in high doses, practical clinical use at present would be *limited*." His conclusion is that "these results should be viewed with caution."

It seems clear then that the administration of high-dosage estrogen preparations within 48 hours of exposure is still in the experimental stage and that Morris' work should not be interpreted as conclusive evidence that these preparations will prevent pregnancy in all instances. It should be remembered that there is no way of knowing whether women raped at midcycle would have become pregnant, since the chance of pregnancy following rape is uncertain for many obvious reasons. There can be no controls. Women, in order to take advantage of this method of preventing these unfortunate pregnancies even if it were to prove uniformly reliable in all instances, would have to be treated by physicians within 48 hours after intercourse.

There are those who demand legal "proof" of criminal assault before they will accept the "alleged" rape and interfere with the pregnancy. How could this proof be obtained within 48 hours of exposure? The legal process is by necessity slow; adjudication within 48 hours is impossible. Many women are reluctant to report cases of rape the moment it takes place, because of the social stigma involved and the failure to prosecute in most cases of rape. I would therefore suggest that even if high-dose estrogen administration could always prevent implantation of the fertilized ovum, the use of this modality would be limited.

There are also serious legal questions involved in administering such medication under Minnesota's present abortion statute, which makes it a felony to "administer to a female, whether pregnant or not, any medicine, drug or substance with intent thereby to produce miscarriage."

Professor Maynard Pirsig, Professor of Law, University of Minnesota, has

rouTINE TB screening with TUBERCULIN, TINE TEST (Rosenthal) Lederle

A method so rapid and
simple that you just swab...
uncap...press...and discard.

Results, read at 48 to 72 hours, are comparable in accuracy to those of older standard intradermal tests. The self-contained, disposable unit requires no refrigeration and is stable for two years. Side effects are possible but rare: vesiculation, ulceration, or necrosis at test site. Contraindications: none, but use with caution in active tuberculosis. Available in boxes of 5 and cartons of 25.

LEDERLE LABORATORIES, A Division of
American Cyanamid Company, Pearl River, N.Y.
448-7-4865

written that "Chitty's Medical Jurisprudence states that the expulsion of the ovum or embryo within the first six weeks after conception is technically called miscarriage. If the use of the term miscarriage is proper, then the meaning of the present statute makes the practice of administering a hormone an abortion. I have found no authorities to the contrary that would lead to a different conclusion."

I would therefore urge the physicians of this state to carefully read Professor Morris' paper and Professor Pirsig's opinion before resorting to the use of high-dosage estrogen to women who have been raped. Let me also respectfully remind those physicians who believe that life begins at the moment of conception that, in order to be consistent, they cannot advocate the use of any drug or substance which will prevent implantation of a fertilized ovum. The moral issue remains whether this is to be done medically or surgically.

In the light of Professor Pirsig's opinion, when doctors of the highest reputation of this state are put in this predicament, acting in accordance with their highest ethical principles, it would seem vitally important that the present abortion statute be changed and changed promptly.

The Editor's Soliloquy

Two Blaud's -- Bed Socks -- Stat!

My hypothetical patient in the hospital with acute hemorrhagic anemia doesn't want all those needles in her arms and legs and those bottles of blood overhead; she wants two Blaud's, Stat! And for that postoperative pulmonary congestion and hyperpyrexia: no tubes down her throat to make her cough her head off; she's catching cold and wants bed socks!

When told to trim down and take off weight: that's O.K. if she doesn't have to cut down on calories. Who wants to deprive oneself? Why can't she have shots instead!

For her little aches and pains why can't she have those daily infra treatments—like the neighbor's wife has been 'enjoying for a year and a half now—exclusive of Saturdays, Sundays, and holidays. If they weren't helping her it stands to reason she'd stop having them, wouldn't she!

Curbstone Consultation

QUESTION: A 32-year-old woman patient of mine was recently in for a checkup. The examination was entirely negative and she was feeling well. However, a serum protein-bound iodine was reported to be 9.0 mcg.%, and repeated was 9.5 mcg.%. A thyroid I^{131} uptake was then done and reported as normal. A T_3 resin test was in the hypothyroid range. She has not received any iodine-containing drugs or x-ray contrast material, and her only medication is "Enovid" for contraception. She has had a small diffuse goiter since her first pregnancy ten years ago. Do you think she has any thyroid disease, and if so what can I do further to make a diagnosis?

ANSWER: First of all, pregnancy is associated with an elevation of plasma thyroid-binding globulin and as a result, an increase in serum protein-bound iodine and a decrease in T_3 resin uptake. The thyroid I^{131} uptake is normal. Small, diffuse, asymptomatic goiters commonly occur during pregnancy. These changes usually return to normal within six to eight weeks after delivery, although the goiter may persist. The administration of estrogens, including the contraceptive pills, produce these same changes except for the goiter.

The abnormalities found in your patient are most likely due to the contraceptive pill she is taking. Stopping the "pill" for four to six weeks and repeating the tests would establish this, although in a clinically euthyroid patient, I do not feel this is necessary. I would, however, make certain she is not pregnant.

Alvin L. Schultz, M.D.
Minneapolis, Minnesota

QUESTION: A 46-year-old man presented with a painless mass, about walnut size, at the base of his neck. He stated that it had arisen over night, and it was slightly tender. A ^{131}I scan revealed an area of hypoconcentration of radioactivity over the mass. Over a period of three weeks the mass became smaller without therapy. At that juncture, it was removed.

ANSWER: At surgery a hemorrhagic adenoma was discovered. The mass was a thin-walled cyst with an organizing hematoma in it.

The sudden appearance of a tender mass in the thyroid should always oblige one to consider the diagnosis of hemorrhagic adenoma.

The Viewing Box

Pyuria with Negative Urine Culture

The films below were made on a sixteen-year-old high school student. Figure 1 is the film made before the injection of the contrast media and Figure 2 is the twenty-minute excretory urogram. This lad was completely asymptomatic. Pyuria was noted on a urinalysis performed as part of a physical examination. A routine urine culture was reported as negative and a ten-day course of sulfisoxazole had no effect on the pyuria. At this point the films were made.

Figure 1

Figure 2

What is your diagnosis? (See next page.)

Diagnosis: Tuberculosis of the right kidney. Both smear and culture of the urine were positive for tubercle bacilli.

Renal tuberculosis is usually asymptomatic until the bladder or the epididymis becomes involved. With a negative routine urine culture and significant pyuria that does not respond to treatment, the diagnosis of tuberculosis should be entertained. The large ring-like calcification (arrow, Figure 1) overlying the right kidney represents a cold abscess. The non-function of the upper pole on the right is a result of tuberculous stricture (arrow, Figure 2) of the infundibulum to the upper pole calyx. Both of these x-ray findings are typical of renal tuberculosis.

Eleventh Annual Fellowship Program Announced by Wyeth Laboratories

Applications for two-year Wyeth Pediatric Fellowships are available now for residencies commencing July 1, 1968, it has been announced by the chairman of the Selection Committee, Philip S. Barba, M.D., past president of the American Academy of Pediatrics. All applications for this, the eleventh group of Fellowships, must be in the hands of the Committee by December 1, 1967.

Sponsored by the Wyeth Fund for Postgraduate Medical Education, each of these fellowships provides \$4,800 over two years toward the advanced training required for board certification in pediatrics. Wyeth's monthly payments, made directly to recipients, are in addition to the usual stipends paid to residents by the institutions in which they train.

Eligible to apply are interns, physicians who have recently completed an internship, research Fellows, or physicians completing their tour of duty with the Armed Services or the U.S. Public Health Service. Applicants must be citizens of the United States or Canada. Those who have already started Pediatric Residency training are not eligible. In the first nine years of this Fellowship program, 176 physicians have received its assistance toward their advanced training.

Each Fellow may choose the hospital in which he will train provided that it is accredited by the Residency Review Committee which represents the American Board of Pediatrics, the American Academy of Pediatrics, and the Council of Medical Education and Hospitals of the American Medical Association.

A voluntary committee of pediatricians, headed by Dr. Barba, Adjunct Professor of Pediatrics at Temple University School of Medicine and Emeritus Associate Professor of Pediatrics at University of Pennsylvania School of Medicine, has the responsibility of choosing the Pediatric Fellows. The committee considers the following factors: evidence of good character, academic achievement, performance of duties, and need for financial assistance. Wyeth plays no part in the selection of recipients.

Wyeth Laboratories inaugurated this Fellowship program in 1958 to encourage interns and other young physicians who want to specialize in pediatrics, who have proven abilities, but who would find it difficult to finance the required post-graduate training.

Heredity is nothing but stored environment.—Burbank

Tumor Conference

Eosinophilic Granuloma

EOSINOPHILIC GRANULOMA belongs to that group of diseases known as the proliferative reticuloendothelioses, histiocytoses, or reticuloses. In addition to involvement of the reticular tissue, there may be widespread systemic involvement including that of lung or bone. The following is the case history of a patient who, when first examined, showed involvement of both lung and bone without other evidence of the disease.

Case Report

A 17-year-old white boy was first seen in January 1966 because abnormalities were noted in a chest film. This chest roentgenogram had been made elsewhere one month previously because of a minor shoulder injury incurred during a school basketball game. The patient was asymptomatic. The only past history of importance was that he had spent several weeks as a "shaver" in a furnace during the previous summer.

The physical examination revealed a vigorous young male in no distress. There were no skin lesions or palpable nodes, and the liver and spleen were not palpably enlarged. The lungs were clear to percussion and auscultation.

Fig. 1—Posteroanterior view of the chest taken four years previously and reported as indicating normal findings.

Fig. 2—Posteroanterior view of the chest taken on admission to the clinic, showing fine, nodular opacities and diffuse, reticular pattern of infiltration.

Continued

The laboratory findings were within normal limits with a white blood cell count of 7500 and a normal differential count. The serum electrophoretic pattern was normal. Results of the PPD skin test, fungal skin tests, and the sputum cytology were negative.

The original film showed finely nodular opacities widely distributed throughout both lungs with a diffuse reticular pattern of infiltration. In addition, a well-defined lytic process involved the first thoracic vertebra. A chest film taken four years previously (Figure 1) was reported normal. A repeat chest roentgenogram (Figure 2) showed abnormalities similar to those described in the presenting film. A coned-down film of the cervicothoracic spine (Figure 3) confirmed the presence of a lesion involving the posterior elements of the first thoracic segment with an intact vertebral body. The skeletal survey revealed no other osseous involvement.

An open biopsy of the laminae and the spinous process of the first thoracic segment was performed. The diagnosis of the pathologist was eosinophilic granuloma, fibrosis and reaction, and new bone and cartilage formation.

Radiation therapy was instituted, and 1500 rads were delivered to the bony lesion. Subsequently, corticosteroid therapy was initiated because of the extensive pulmonary involvement. The patient was still asymptomatic six months later. A follow-up chest film (Figure 4) showed an apparent improvement in the bone lesion, while the pulmonary findings were unchanged.

Discussion

The pathological indications of eosinophilic granuloma of bone have been well described in several reports.^{1,2,6} The basic lesion is localized in the medullary cavity of the bone; as it expands it erodes and perforates the cortex and may then involve neighboring soft tissue. Thus the picture may be very similar to that of a malignant bone tumor.

Extraskelatal Disease

Although the term eosinophilic granuloma was originally applied to bone lesions with eosinophilic and histiocytic infiltration,⁶ extraskelatal manifestations have been recognized,⁸ and indeed it is now accepted that 20 per cent of all such bone lesions have associated pulmonary involvement.¹⁰ This has been demonstrated by lung biopsy or, as in our patient, by bone biopsy. The spectrum of pathological changes in the lung has been described in several reports.^{4,5}

Fig. 3—Coned-down study of cervicothoracic spine showing lytic process involving first thoracic vertebra.

Fig. 4—Posteroanterior view taken at follow-up visit six months after first being seen. Findings are essentially unchanged from those on film taken at first admission.

The roentgenographic changes of eosinophilic granuloma in bone have been reviewed by Ochsner.⁸ The initial lesion is a localized area of rarefaction. The defect does not have a rim of sclerosis and represents the granuloma which has destroyed the bone. This looks very similar to the rarefaction due to other causes, and the distinction can only be made, as in our patient, by bone biopsy.

In the lung the roentgenographic changes show marked variability and may simulate many other diffuse infiltrative diseases.³ The picture may be one of generalized miliary infiltration, coarse nodulation, or reticulation. However, these changes can be limited to focal areas in the lung.⁵ Later changes include progressive fibrosis, perifocal emphysema, and "honey-combing."⁴ Subpleural bleb formation is believed to be responsible for the frequency of spontaneous pneumothorax as a complication of this disease.^{7,9}

Therapy and Prognosis

Most of the cases of eosinophilic granuloma are seen in childhood, adolescence, or early adult life. This condition usually causes some pain, though as a rule the pain is not severe.

Biopsy is generally required for a correct diagnosis.

According to Aegerter and Kirkpatrick,¹ this condition is usually regarded as an innocuous one, with the results of conservative treatment being good. It is important not to overtreat this type of benign tumor in the mistaken assumption that a malignant process is present.

Treatment is usually curettage with or without postoperative radiation therapy in moderate dosage.

Recently these patients have been treated with cortisone and various antimetabolic drugs with some degree of success.

However, the prognosis should be guarded if osseous as well as extraosseous lesions are present.

Summary

Eosinophilic granuloma may involve many systems, with simultaneous involvement of lung and bone. Our patient was entirely asymptomatic; diagnosis was established by bone biopsy. Therapy included radiation and corticosteroids.

Fads

Most medical fads are like some women's fashions—frail, fickle and costly.

—Noah Fabricant

Life-saving words. Required by Congress to appear on all packages of cigarettes.

Unquestionably an important step forward in the dramatic battle to decrease the mortality and morbidity from cigarette smoking.

But in the nation's efforts to reduce death and disease related to cigarette smoking, the most significant influence—the key figure—is you, doctor. The advice of the physician in matters of health is more authoritative and persuasive than that of anyone else.

In the area of cigarettes and health, the importance of the physician's attitude and his *personal action* cannot be overemphasized. That he has indeed taken personal action is indicated by the impressive statistic showing that only 30% of the doctors in America are cigarette smokers today!

The American Cancer Society's concerted educational campaign on the hazards of cigarette smoking—plus government regulations—will be major factors in guiding each person's approach to this problem.

But in the final analysis, doctor, it is *your* words that your patients will heed. It is you who have the best chance of actually helping an individual to stop smoking or to prevent him from starting.

Caution: Cigarette Smoking May
Be Hazardous to Your Health

Neurological Conference

Idiopathic Epilepsy^{*}

Case Report

Doctor Todd Davis:**

This 18-year-old-boy was first seen at the University Medical Center in March, 1966, with the chief complaint of having had a convulsion three weeks previously. His first seizure occurred in June, 1962, and was accompanied by amnesia for events immediately preceding the attack. His brother told him that he had lain stiffly and then begun to shake all over. Following the seizure the patient was dizzy and lethargic. He had bitten his tongue but had not been incontinent. No apparent cause for his seizure was found at that time; nevertheless, his family physician placed him on $\frac{1}{2}$ grain phenobarbital three times daily as a precautionary measure.

In September, 1962, when he was evaluated at another clinic, no seizures had occurred since the initial attack. Although both the neurological examination and skull x-rays were normal, an electroencephalogram showed a generalized dysrhythmia in the temporal areas bilaterally. Since no obvious cause for his seizure had been found, it was elected to maintain him on the same phenobarbital dose.

Between September, 1962, and February, 1966, there apparently had been frequent intervals during which the patient neglected his medication. Although he was unable to relate a detailed history of his seizures, he undoubtedly has had several generalized seizures. Approximately three weeks before his visit to our Center in February, 1966, he had had another grand mal convulsion. At that time he had not taken his medication for one week preceding the seizure. In addition, he had been up quite late the night immediately prior to the attack and had only a little sleep the previous night. On the morning of that seizure he had had three lapses of consciousness lasting for five seconds each, then the generalized seizure occurred. When he awoke he found that his tongue was sore and he felt very tired; so he immediately went to bed. Finally his mother insisted that he go to the doctor.

Family History

Although the patient does not know any details of his birth history, he has had no other significant head trauma. In regard to childhood diseases, he has had both measles and mumps without complication and there has been no history of meningitis. It is interesting that three of his six siblings also have had seizures. At least two of the siblings had minor seizures which eventually progressed to major type seizures. A third sibling has had only grand-mal seizures.

Neurological Examination

Neurological examination of the patient in February, 1966, was completely within normal limits. His skull films showed no abnormality, but some slowing and depression of activity was evident in the right temporal area on the electroencephalogram. Again it was decided

^{*}Neurological Conference held February 23, 1967. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals.

^{**}Student Doctor, University of Minnesota Hospitals.

Continued

to continue him on the same phenobarbital dosage.

Progress

Four or five weeks later the patient came to the clinic stating that he had had two transient lapses of consciousness a few days earlier. He noted that he had been up late the preceding night and had forgotten to take his phenobarbital. Subsequently, in May, 1966, he stated that he was taking about two pills a day rather than three and also readily admitted that he frequently forgot to take his medication. Since he was complaining of symptoms of tiredness, his medication was changed from phenobarbital to a combination of dilantin and mebaral.

Another generalized convulsion occurred prior to his visit to our medical center in late October, 1966. Preceding this seizure he had forgotten to take his medication for a three-day period; however, as long as he took his dilantin and mebaral regularly, he had been seizure free.

During his most recent visit in late January, 1967, the patient stated that he had been taking his medications regularly and had had no seizures. He had brought a medical form which he wanted us to certify in order for him to obtain a driver's license. Also he was to be graduating from a vocational high school which he had been attending in Minneapolis and had already obtained a job with an electronics firm in the Twin Cities. Interestingly, there were only two students out of an original 35 that finished the electronics course from this vocational high school. He said that he liked mathematics and science, and expressed some interest in going on to college.

Neurological Evaluation

Dr. Robert Soll:*

This patient's convulsive disorder would be classified in the group known as idiopathic or essential epilepsy in contrast to the symptomatic type in which the cause is known. Although it is now believed that a genetic or hereditary factor is present in all forms of epilepsy, a significantly higher incidence of seizures occurs in families of patients with idiopathic epilepsy. This patient and his siblings demonstrate a typical example of this correlation. The prevalence of affected individuals among parents and siblings of patients with centrencephalic seizures was thirteen per cent compared with only two per cent in the control group.¹

I was impressed with the fact that this patient's convulsive seizures undoubtedly would be well controlled if he took his medications regularly. On the other hand, if his seizures definitely were uncontrolled by medication, a pneumoencephalogram should be considered. In caring for him medically, we may share the blame for his neglect of medications by not having continually attempted to explain the nature of seizures and their treatment. Thus we may have failed to give the patient as complete an insight into his disability as may have been possible. Also there is a marked variability in patients, and both their personality and intelligence may profoundly affect their response to treatment.

Psychological Evaluation

Mr. William Gayton:**

In the light of the patient's medical history we felt that an evaluation in the areas of intelligence, cerebral dysfunctioning and personality would help delineate the factors involved.

Intelligence

Intellectual estimates were obtained from the Binet Vocabulary and the Porteus

*Neurologist, University of Minnesota Hospitals.

**Clinical Psychology Trainee, University of Minnesota Hospitals.

Mazes. The patient obtained an I.Q. of 88 on the Binet Vocabulary and a I.Q. of 114 on the Porteus Mazes. The Binet estimate is primarily a verbal measure of abstract and conceptual abilities. Therefore, his score places him in the low average range of intellectual functioning. The estimate from the Porteus Mazes indicates that his foresight and planning abilities are slightly above average. These results suggest that in the practical applications of intelligence the patient could be expected to do quite well; however, he would be somewhat limited in abstract thinking or in the tasks that call for complicated reasoning. Plans for a college education should be altered on the basis of such results. Although he should do fairly well in a vocational type setting, I have serious doubts as to his ability to achieve in a college setting.

The patient was given the Graham Kendall Memory For Designs in order to assess those behaviors related to cerebral dysfunctioning. He achieved a perfect score on this instrument which indicates that he has no problems in short-term memory or in the ability to integrate perceptual-motor activities.

The patient's MMPI profile is mild to moderately abnormal. It suggests the presence of acute anxiety and considerable emotional turmoil. There is also a certain amount of depression, social introversion, and social withdrawal. He appears to be a passive, immature individual with rather poor ego strength. Since he tends to be somewhat sensitive and suspicious of the motives of others, he could be very difficult to manage if he thought that others were trying to manipulate him. Some of these behaviors may be related more to situational factors than to internal conflict.

Dr. Soll:

Do you feel that the internal conflict suggested by the MMPI is significant enough to be evaluated further psychiatrically?

Mr. Gayton:

Yes, I think a psychiatric interview in regard to his present emotional functioning would be helpful if he is having problems that he isn't disclosing.

Social Service Evaluation

Miss Helen Kretchmer:*

We often have an opportunity to talk to other members of a patient's family, but in this case we do not. Since the patient has been living in Minneapolis for almost one and one-half years, he came to the University Hospitals unaccompanied by other members of his family. He is a nice-looking, pleasant young man who gives the impression of having much nervous energy and a need to be constantly active. During the interview he handled any uncomfortable subject by laughing. I believe that he felt grown up and responsible for himself. He appeared to deny any concern that he might have about his seizure condition.

Parental Relations

He readily discussed his father, a man in his early fifties and a publisher of a small-town newspaper. Although his father has diabetes, he has worked long hours. The patient felt that this has been very difficult for his father. Very little was said about his mother.

There are five siblings, two of whom are still at home. An older brother, who has had two years at Mankato State College, works at the postoffice in the Cities. His older sister also attended Mankato State College, the University of Minnesota and the University of California. She is married and has two children. In her

*Supervisor, Social Service Department, University of Minnesota Hospitals.

Continued

spare time she does tutoring. Another older brother who is in the army now has had three years of college. Thus one can understand why this young man is considering the possibility of going on to college.

Since the age of 10, the patient has operated his father's presses for the newspaper. At the age of 16 he persuaded his father to buy a \$5,000 German press. When the man came from Germany to instruct them concerning its operation, the father was too busy; so the patient learned the details. Since the father still hasn't learned to operate the press, the patient goes home almost every weekend to help his father. A certain amount of pressure was involved because payments on the press had to be made. At the present time the patient is teaching his 15-year-old brother how to operate the press.

Work Schedule

The patient obtained his present job at an electronics firm last March, 1966, and has just now started working full time. While at the vocational school he was working for this firm a few hours a day. Now he has long working days every day of the week, besides going home to work weekends for his father.

The patient's hobby is hunting. His future plans are to work for a while on his present job and then leave for Alaska with a friend. As far as finances are concerned, the patient has been paying his own way for several years. I was rather interested in the fact that he felt responsible for the bill which was incurred by him for his medical evaluation in 1962.

His vocational high school counselor has advised him to pursue an electronics career. Apparently he was a D student in theoretical courses but averaged C or above in the laboratory courses. His Strong Interest Test indicated him to be high in mathematics and science. Although he was rated as having a somewhat low I.Q. in high school, he was in the middle half of the class on the Air Force test, scoring an 85. The vocational high school training was provided free of tuition. His own instructor said that he generally was a good worker and compared well with others. No real problems existed during his vocational training; however, he was satisfied with less than a good performance at times. The patient had told his instructor that he had a seizure problem. In retrospect, he may have been having more problems than he was aware of. On occasion the instructor drew a blank response from him when he seemed to have forgotten everything that he knew. At other times he appeared groggy or sleepy. These episodes would pass, however, and he would be all right again.

When the patient was still in high school, he purchased a new car. Later he completely demolished it in an accident while driving back from Canada, and now he cannot afford to drive, probably because he still owes money on the car. He would like to be in the Army—even if it were only on limited service. He felt that it would be an interesting experience.

He admitted that he forgets to take his medication at times but said that he would try to do better. Outwardly the patient manifests some of the anxieties that persons with seizures often have. As stated earlier he should have better awareness and better understanding of his condition in order to recognize his need for continued care. Very likely he is unable to foresee now the types of problems that may arise in the future.

Dr. Soll:

Your description of the patient appears to be one of a reliable individual who has helped his parents and has become quite independent. His seizures may repre-

sent to him an obstacle which detracts from his self reliance. In this light he probably dislikes being dependent upon his anticonvulsant medications.

Mr. Gayton:

It is a very interesting possibility that his self concept cannot accept the idea that he has to be dependent upon something in order to function adequately. The drugs themselves can be a sign of weakness to some people.

Dr. Soll:

The fact that he recently requested a statement concerning his health which would permit him to obtain a drivers' license shows a considerable lack of insight by him into his seizures.*

One way of managing this patient would be to see him frequently in order to give him the supportive care, understanding and reassurance that he needs. This could be accomplished by clinic visits at least every two weeks for a few months. In this way he could develop confidence in us. If he has other problems he may then be able to discuss them more readily also.

Voice:

Should a patient have told his employer that he has a seizure disorder?

Dr. Soll:

This has to be the patient's decision. Unfortunately, many employers are unwilling to accept a person who has seizures, particularly when other people who do not have seizures are readily available for jobs.

Miss Kretchmer:

I assume that the patient is an excellent worker. There should be a considerable opportunity for him almost anywhere. Sometimes an employer will overlook quite a lot if one is a good worker.

Conference Recommendations

1. The patient should be seen in clinic at frequent intervals in order to develop a better understanding of his condition and to promote reliability in taking his medications. Visits every two weeks are recommended.
2. A psychiatric referral should be made for the purpose of evaluating further possible emotional conflicts the patient might be having.
3. Any recommendations regarding a college education should be deferred temporarily. More intensive psychological studies may be undertaken if the patient eventually considers college seriously.

Robert Soll, M.D.
University of Minnesota Hospitals

*The state law requires that a patient be seizure-free for two years before being allowed to obtain a driver's license.

Participating in the conference were: Dr. Robert Soll, Neurologist; Miss Helen Kretchmer, Supervisor, Social Service Department; Student Doctor Todd Davis, and Mr. William Gayton, Clinical Psychology Trainee.

Obesity

From the day on which she weighs 140, the chief excitement of a woman's life consists in spotting women who are fatter than she is.

—Helen Rowland

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years — prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical

facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients — the common goal of medical and pharmaceutical research — toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

The Physician's Workshop

Lupus Erythematosus Cell (LE-Cell) Test without A Blood Clot

MANY TECHNIQUES have been devised for the demonstration of the lupus erythematosus cell (LE-Cell) since Hargraves, Richmond, and Morton¹ reported the presence of amorphous cytoplasmic inclusion bodies in leukocytes in the bone marrow of patients with systemic lupus erythematosus.

The Blood Clot Technique

The most widely used tests are the blood clot tests of Zimmer and Hargraves,² and Magath and Winkle,³ which often produce "pseudo lupus erythematosus cells." But these may be difficult to separate from true lupus erythematosus cells by an occasional observer. Thus a lupus erythematosus clot preparation may be reported positive when actually negative. Further, lupus erythematosus clot tests may vary from positive to negative over a period of twenty-four hours.

The Heparinized Blood Technique

Zinkham and Conley⁴ showed that in-vitro lupus erythematosus cell production depends upon three factors: (a) actively phagocytic leukocytes, (b) amorphous nuclear leukocyte material, and (c) the presence of the lupus erythematosus factor. They devised a glass bead-rotary method which gives reproducible results. By traumatizing nonviable leukocytes high yields of amorphous material and lupus erythematosus cells are obtained. Further, their technique produces lupus erythematosus cells when the blood clot tests are negative.

Briefly the Zinkham-Conley technique is as follows: Heparinized venous blood is allowed to stand for two hours; transferred to a flask containing 15 glass beads 4 mm. in diameter, and placed on a rotator for 30 minutes. About 1 ml. of the blood sample is transferred to a Wintrobe hematocrit and centrifuged for 10 minutes at 1,000 r.p.m. Several smears are made from the buffy coat, allowed to air dry for one to two hours, and then stained with Wright's blood stain.

The increasing use by clinicians of the lupus erythematosus cell test has created a problem in many medical laboratories because of the 3½ to four hours necessary to complete the Zinkham-Conley procedure. We have worked out a modification of their technique, reducing the time to 1½ hours. The test retains the high degree of sensitivity yield of amorphous material, lupus erythematosus cells, leukocyte rosettes, and clearance of cellular morphology of the Zinkham-Conley technique. Production of pseudo lupus erythematosus cells is practically nil.

Method

Draw 5 to 7 ml. venous blood into a heparinized 10 ml. B-D Vacutainer tube, invert several times and place 10 glass beads 6 mm. in diameter in the tube. Secure the tube on a rotator and allow to revolve at 25 r.p.m. for 30 minutes. Let stand at room temperature for 30 minutes. Invert the tube several times and centrifuge at

Continued

1,000 r.p.m. for five minutes.

With a Wintrobe pipette remove some plasma and place it in a small test tube. Leave enough plasma over the leukocyte concentrate to permit easy skimming of the buffy layer including a small amount of the uppermost layer of erythrocytes, since lupus erythematosus cells tend to settle at the bottom of the leukocyte column. Expel the sample onto a paraffin-coated watchglass and mix the specimen well with a thin glass rod or a Wintrobe pipette. If the sample is too concentrated, dilute with the spare plasma.

Place a small drop of the specimen on a clean microslide and spread it out to blood smear thickness. Make three smears. Whip rapidly through the air. When dry apply Wright's blood stain for three minutes. Add enough distilled water short of overflow, and mix well by placing a wooden applicator on one end of the slide. Move the applicator up and down on the stain surface for several seconds. Allow the stain to act for five minutes. Rinse with distilled water, and dip the slide into a decolorizer for five seconds (methyl alcohol 5 ml., acetone C.P., 0.5 ml., distilled water 100 ml.). Wash the slide with distilled water and permit it to air dry. Place immersion oil on the smear and press a coverslip over the oil. Survey the smear with the high dry objective beginning at the edges of the smear. The test is positive when only one typical lupus erythematosus cell is observed.

Discussion

According to Dubois⁵ the lupus erythematosus cell test is the mainstay for the diagnosis of systemic lupus erythematosus regardless of the advances made in anti-nuclear antibody tests. While nuclear material of nonviable leukocytes is the source of the amorphous matter present in the lupus erythematosus cell, the process of being phagocytotic seems to depend upon its physical-chemical properties. Dubois, using the heparin, glass bead-rotary technique on 502 proven cases of systemic lupus erythematosus, found 23 per cent had amorphous material only. While it appears that the lupus erythematosus cell factor is an antibody reacting with desoxyribonucleoprotein (DNP) of degenerated leukocyte nuclear material, McDuffie⁶ states that "not all patients with positive lupus erythematosus clot tests have a detectable anti-DNP in their sera. Whether the fact that not all patients with an anti-DNP give a positive lupus erythematosus clot test is due to quantitative differences in the amount of antibody present or to other factors is not known." That the lupus erythematosus cell factor is active in vivo was shown by Schleicher.⁷

In our hands the Zinkham-Conley technique proved superior to the lupus erythematosus clot tests and the results closely correlated with the clinical manifestations of lupus erythematosus. These observations dovetail with those of Dubois,⁵ with whom we agree⁸ that the most characteristic lupus erythematosus cell is found in preparations made from heparinized blood processed by the glass bead-rotary technique.

Conclusion

A routine test to demonstrate the lupus erythematosus cell is presented. The method takes 1½ hours to complete. The test yields amorphous material, lupus erythematosus cells, leukocyte rosettes, and clearness of cellular morphology.

Professional Courtesy**Adopted by Judicial Council***

The following guidelines are offered as suggestions to aid physicians in resolving questions related to professional courtesy.

1. Where professional courtesy is offered by a physician but the recipient of services insists upon payment, the physician need not be embarrassed to accept a fee for his services.

2. Professional courtesy is a tradition that applies solely to the relationship that exists among physicians. If a physician or his dependents have insurance providing benefits for medical or surgical care, a physician who renders such service may accept the insurance benefits without violating the traditional ethical practice of physicians caring for the medical needs of colleagues and their dependents without charge.

3. In the situation where a physician is called upon to render services to other physicians or their immediate families with such frequency as to involve a significant proportion of his professional time, or in cases of long-term extended treatment, fees may be charged on an adjusted basis so as not to impose an unreasonable burden upon the physician rendering services.

4. Professional courtesy should always be extended without qualification to the physician in financial hardship, and to members of his immediate family who are dependent upon him.

Medical Seminar

Roentgenologic Bone Changes in Blood Dyscrasias and Gaucher's Disease

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

DAVID B. LEWALL, M.D.*
Rochester, Minnesota

The Anemias

THALASSEMIA MAJOR (also called Cooley's, Mediterranean, and erythroblastic anemia) is a hereditary disease in which decreased amounts of heme and globin are synthesized, so that the erythrocytes are microcytic and hypochromic. The erythrocytes, which are not produced at a normal rate, are destroyed prematurely by the reticuloendothelial system, and anemia results. The skeletal changes are due to accelerated hematopoiesis, which causes exuberant growth of the marrow. The earliest changes occur after the first year of life and are seen in the small bones, especially the metacarpals and the metatarsals. In later childhood and early adulthood, the active red marrow tends to recede toward the trunk, and hypoplastic yellow (fatty) marrow is left peripherally, so that the early changes in the distal parts of the tubular bones disappear. At this stage the skull, spinal column, and pelvis tend to show the greatest change. Skull changes are more common and more striking in thalassemia than in any of the other anemias. The diploe is widened; the outer table is displaced outward, and it is often thinned

(Figure 1). The diploic trabeculae may become perpendicular to the tables, and this produces the so-called hair-on-end appearance. The occipital squamosa is always spared inferior to the internal occipital protuberance, presumably because of the normal lack of red marrow in this region (Figure 1). Overgrowth of marrow in the maxillary, sphenoidal, and temporal bones may inhibit pneumatization of the paranasal sinuses and mastoids. Roentgenologically, this is most evident in the maxillary antra. This finding is almost exclusive to thalassemia, and therefore when it is encountered in association with the previously mentioned changes it is virtually pathognomonic. Swelling of the maxillae occasionally displaces the orbits laterally and causes ocular hypertelorism. The tubular bones show coarse trabeculation (chiefly as a result of destruction of the finer trabeculae), pressure atrophy of the cortices, and swelling of the shafts which gives the bones a squared-off appearance (Figure 2). The spinal column may show reticulation and some osteoporosis, but the cupping and compression of the vertebral bodies that are features of sickle-cell anemia do not occur.

Sickle-cell anemia too is characterized by abnormal erythrocytes that are lysed prematurely.

Continued

*Mayo Graduate School of Medicine (University of Minnesota): Resident in Radiology.

The bone lesions are due in part to hyperplasia of the marrow and in part to infarction of bone. Although diploic widening in the calvarium occurs, radial spiculation is rare. In the long bones the medullary spaces are widened and the cortices are thinned. Coarse trabeculation is often seen.

Fig. 1—Thalassemia major. The diploe is markedly widened, and there is radial spiculation. The squamosa below the occipital protuberance is characteristically spared.

An important finding is demineralization of the spinal column. This may be found even in children; in older individuals it often leads to biconcave compression of the vertebral bodies. Moseley¹ contended that the discovery of osteoporosis of the spinal column together with bone infarction and cortical thickening is virtually diagnostic of sickle-cell disease. Infarction of bone in children may cause periosteal thickening or elevation, or there may be frank infarctive changes in the shafts, especially at the ends. Occasionally there is massive infarction of a long bone, suggesting osteomyelitis from a roentgenologic point of view. Gangrene not uncommonly results. In adults, infarction tends to involve the ends of long bones or localized areas in the medulla. The femoral head and less often the humeral head may collapse after infarction. The change seen in the femoral head is indistinguishable roentgenologically from aseptic necrosis due to other causes.

Congenital spherocytosis is a hereditary hemolytic anemia in which spherocytes appear in the peripheral blood. Splenectomy cures the hemolytic process. The roentgen manifestations depend on the same mechanism as in Cooley's anemia—marrow hyperplasia—but the anemia is

Fig. 2—Thalassemia major. The trabecular pattern is coarse, the cortices are thinned, and there is slight squaring-off of the bones.

usually not as severe in hereditary spherocytosis, and the disease usually becomes overt later in life when the peripheral portion of the skeleton is no longer involved in erythropoiesis. Consequently, bone changes are not common, and changes in the tubular bones are distinctly uncommon. When changes are encountered, these are usually in the skull. They are similar to the changes in thalassemia, but less extensive.

Other congenital hemolytic anemias, including hereditary elliptocytosis and the various enzyme abnormality states such as pyruvate kinase deficiency, may cause changes in the calvarium. Iron-deficiency anemia was reported for the first time in 1958² to be a cause of these skull changes, occasionally with radial spiculation. Curiously, the severity of the bone changes apparently does not correlate with the severity of the anemia. No changes have been described in other parts of the skeleton. Recently, secondary polycythemia due to congenital heart disease has been recognized as a cause of similar skull changes.

The Fanconi syndrome consists of anemia, leukopenia, thrombocytopenia, and a series of inconstant congenital defects, the most common of which are hypoplasia or aplasia of the thumb and first metacarpal bones, syndactylism, microcephaly, and ectopia of the external auditory canals. There is nothing diagnostic about these findings, but their presence may serve to suggest the diagnosis in an anemic child. This syndrome is not to be confused with another Fanconi syndrome consisting of cystinosis and refractory rickets.

Leukemia

The incidence of roentgenologically demonstrable bone lesions in childhood leukemia is usually stated to be between 50 and 75%. In adult leukemia it is generally held to be less than 10%, although in the series studied by Silverstein and Kelly³ it was higher. It is notable that the incidence of bone changes is higher in children because their entire marrow space is occupied by blood-forming tissue, so that there is little room for the proliferating leukemic cells, which soon encroach on the bone itself. Adult marrow, being largely fatty, can absorb a large mass of leukemic tissue before the bone itself is destroyed.

The atypicality of the clinical course in children, especially the frequently deceptive onset, makes any aid to diagnosis of more than just academic interest. Leukemia in childhood often

presents with joint pain and even swelling and tenderness, so that the initial diagnosis is often rheumatic fever or juvenile rheumatoid arthritis. The early blood picture frequently shows a normal white cell count, and indeed the white cells may even be diminished in number. Thus, the roentgen findings may be the first indication of the true nature of the disease. These findings in the child will be discussed first.

The roentgen signs of leukemia are (1) the transverse metaphyseal line, (2) osteolytic lesions, and (3) periosteal lesions. The most common and perhaps the most useful sign is the transverse metaphyseal line (Figure 3-A). This line occurs in the metaphysis adjacent to the epiphyseal plate. It tends to be thin and usually extends right across the bone from cortex to cortex, although in some early cases the line is incomplete. It is most often encountered at the knee, although it may be seen in any of the long bones when rapid growth is taking place and even in certain flat bones such as the ilium, just beneath the cortex. The pathologic basis for this finding

Fig. 3— (A) Childhood leukemia. Note the transverse metaphyseal lines at the knees and ankles. (B) Leukemia in another child. Periosteal reaction is seen along the humeral shaft, and osteolytic lesions are present in all of the bones.

Continued

is not clear, but it may be due to a failure of new enchondral bone formation secondary to the child's poor general health. Microscopic examination of this line has failed to demonstrate leukemic infiltration as the cause. The line is not specific for leukemia, for it is occasionally seen in children with metastatic neuroblastoma, scurvy, syphilis, or acute infections and, though rarely, in apparently normal children. When seen, however, it should alert the clinician to the probability of leukemia.

Osteolytic lesions are the most common finding in childhood leukemia (Figure 3-B). These may present as extensions of the transverse metaphyseal line or may originate *de novo*. The spongiosa is usually affected, but in the early case the cortex is generally spared. Eventually the entire shaft becomes involved, and generalized demineralization occurs. The cortex may show areas of destruction, most often in the long bones but also in the skull and pelvis. In the skull increased intracranial pressure may be seen with decalcification of the sella and spreading of the sutures. There is often an apparent coarsening of the trabeculae of long bones due to destruction of the finer trabeculae. This is accentuated by the destruction of the overlying cortex. Instead of regions of osteolysis, there may be a generalized demineralization.

Periosteal changes are quite common, and they are the usual cause of limb pain (Figure 3-B). These changes are caused by the proliferation of leukemic cells between the cortex and the periosteum, the result being elevation of the periosteum and sometimes periosteal new bone formation. Despite the tendency of leukemic patients to hemorrhage, it is uncommon for the periosteal elevation to be due to bleeding. This process occurs most often in long bones, but it is also seen in the short tubular bones of the hand and foot and in the ribs.

In the adult the same findings described for childhood leukemia are seen, although far less often. The very useful sign of the translucent metaphyseal line is rarely seen in the adult. The differential diagnosis of skeletal involvement in leukemia should include consideration of metastatic neuroblastoma, malignant lymphoma, and juvenile rheumatoid arthritis. Metastatic neuroblastoma and lymphoma may actually be quite indistinguishable from leukemia.

Myelosclerosis

Myelosclerosis, a blood disorder of middle and late life, is characterized by fibrotic or sclerotic changes in the bone marrow, marked splenomegaly, and often hepatomegaly. It is sometimes superimposed on long-standing polycythemia rubra vera. Of the many synonyms for this disease, the most common are myelofibrosis and agnogenic myeloid metaplasia with myelofibrosis. Perhaps the term "myelosclerosis" should be reserved for cases involving increased bone density. Early in the disease the marrow is hyperplastic, having a moist, red, succulent appearance. Later, marrow atrophy dominates, and fibrous tissue replaces the marrow; eventually this fibrous tissue calcifies. In effect, there are encroachment of the spongiosa on the marrow space and progressive obliteration of the marrow. The trabeculae become increased both in number and in thickness.

In one third to one half of all cases there are roentgenologically demonstrable bone changes. Tutton⁴ concluded that two kinds of bone change were present. The first, and more common of the two, consists of increased bone density (Figure 4). The second combines increased density with a large number of radiolucent areas (Figure 5). The first form consists of a spectrum from a slight increase to a marked increase in density in which the trabecular pattern is no longer discernible. The contour of the bones is not affected, and the involvement is rather homogeneous except for the greater involvement of the central portion of the skeleton. Extensive involvement distal to the elbow or the knee is distinctly uncommon. In mild cases the cortical-cancellous differential is present but reduced; in advanced cases it may be lost. This change is best appreciated in the medial ends of the clavicles and in the ribs.

The second type of bone change combines the features just mentioned with numerous radiolucencies which are usually elliptical and which measure 2 mm. by 3 or 4 mm. A finding that may be confusing is that the trabecular pattern is actually more distinct than it is normally in the upper part of the femora and the humeri and in the superior part of the acetabula. There are no skip areas that are spared by the lytic lesions, so that if one area of the central skeleton is involved, the entire central skeleton is involved. These lytic areas are probably due to fibrous tissue proliferation and islands of hematopoiesis.

Fig. 4—Myelosclerosis of the sclerotic type. (From Pugh, D. G.: *Roentgenologic Diagnosis of Diseases of Bones*. Baltimore, Williams & Wilkins Company, 1951, p. 484. By permission of Williams & Wilkins Company.)

Fig. 5—Myelosclerosis of the combined lytic and sclerotic type. The appearance of the ribs is not unlike that sometimes seen in myeloma and metastatic carcinoma. Compare with Figure 4.

Because the changes are most extensive in the central portion of the skeleton, the diagnosis is often suggested on chest or abdominal roentgenograms, especially if an enlarged spleen is seen.

Myelosclerosis must be distinguished from osteopetrosis, osteoblastic metastases, fluoride osteosclerosis, urticaria pigmentosa, multiple myeloma, and Paget's disease. If more than a localized area of the skeleton is examined, there should rarely be any difficulty in distinguishing these diseases from myelosclerosis.

Osteopetrosis is a disease of children who rarely survive into adulthood; therefore this diagnosis in an adult should be highly suspect. It is characterized by a general increase in bone density with loss of the internal roentgen anatomy of the bone, so that the cortex, medullary cavity, and epiphyseal plates are obliterated. The ends of long bones are often clubbed, and there may be transverse or longitudinal striations in the bones. The vertebral bodies have a characteristic appearance in the lateral view, namely dense superior and inferior plates with a normal-appearing centrum.

Osteoblastic metastases (usually prostatic) are rarely distributed so evenly as to cause difficulty in diagnosis. On a single film, myelosclerosis may be simulated, but a bone survey allows the differentiation to be made easily.

Fluoride poisoning is encountered in several well-known regions of the country. Also, there is often ligamentous calcification in the pelvis; and splenomegaly does not occur.

Urticaria pigmentosa is distinguished on the basis of the clinical and laboratory data.

Multiple myeloma may give the appearance of the mixed type of myelosclerosis, but in myeloma the bone density is not increased, pathologic fractures occur (they do not in myelosclerosis), and the spleen is not enlarged.

Paget's disease rarely causes difficulty, for the trabecular pattern, the expansion of bone, and the limited skeletal involvement are all characteristic of the disease.

Urticaria Pigmentosa

Urticaria pigmentosa, or mastocytosis, is an uncommon disease which has been receiving the attention of roentgenologists for only a few years (Figure 6). It is a systemic malady which always involves the skin and frequently involves the bone marrow, lymph nodes, and viscera. Clini-

Continued

cally it is characterized by skin pigmentation that urticates readily, so that dermatographia is possible. Large deposits of mast cells are present in the involved tissues, and their high histamine content is presumably responsible for the urtication. Sagher and associates⁵ first reported bone changes in urticaria pigmentosa in 1952. Stark and co-workers⁶ were the first to correlate the roentgen changes and microscopy. They showed that there are areas of bone marrow replacement by dense aggregates of mast cells and associated areas of reactive new bone formation. Sagher and Schorr⁷ established a central registry for the collection of the roentgen manifestations of the disease, and from this they concluded that the bony lesions were of two types—localized and generalized. However, none of the localized lesions were subject to biopsy, and the findings were rather vague; for the present, therefore, it is probably best to consider only the generalized type of bone changes.

These changes consist of generalized cystic osteoporosis of the ribs, thickened bony trabeculae, cranial stippling, and thickening of the tables of the skull and generalized sclerosis of the vertebrae and pelvic bones. In some cases roentgen examination of the gastrointestinal tract reveals diffuse mucosal changes due to infiltration by mast cells.

Multiple Myeloma

Multiple myeloma is characterized by malignant proliferations of plasma cells. Two forms have been recognized—solitary and multiple—but, given time, the solitary form usually matures into multiple myeloma. The clinical manifestations of multiple myeloma are protean and well known and need not be repeated here. It should be emphasized that intravenous excretory urography is contraindicated in myeloma, for this procedure often precipitates acute renal failure.

Roentgenologic bone changes are present in 75 to 95% of cases of myeloma. Classically one encounters "punched out" areas of bony destruction (Figure 7), which are best seen in the skull. These may occur in any bone, although they are rarely seen in the vertebrae. There is virtually never any bony condensation at the margins of these lesions (Figure 7), and the trabecular structure is completely destroyed. Lytic metastases are rarely as well circumscribed as the punched-out lesions of myeloma are. Another helpful point of

Fig. 6—Urticaria pigmentosa. Note the resemblance of the ribs to those in Figure 5. There are also changes in the left humerus and scapula.

Fig. 7—Multiple myeloma. There are characteristic "punched out" lesions in the pelvis and expanding lesions in many of the ribs. Note the absence of marginal sclerosis. (From Pugh, D. C.: *Roentgenologic Diagnosis of Diseases of Bones*, Baltimore, Williams & Wilkins Company, 1951, p. 488. By permission of Williams & Wilkins Company.)

distinction is that occasionally there is an associated soft-tissue mass in myeloma, especially adjacent to the ribs; this almost never occurs in metastatic bone disease. Quite often, involved ribs are expanded, and in the absence of a soft-tissue mass, the differential diagnosis must include fibrous dysplasia, hyperparathyroidism, metastases, aneurysmal bone cyst, and histiocytosis X. When a soft-tissue mass is present, the differential diagnosis is between myeloma and primary malignant disease of the rib such as Ewing's sarcoma, chondrosarcoma, and reticulum cell sarcoma.

In other areas of the skeleton, hyperparathyroidism may be simulated, although subperiosteal resorption of bone never occurs in myeloma. The bone lesions of myeloma tend to cause pathologic fractures, especially of ribs and vertebrae. Pugh⁸ has pointed out that in metastatic bone disease involving the head, the mandible is usually spared.

In myeloma, on the other hand, the calvarium and the mandible may be involved equally.

A very important and rather constant finding is demineralization, which may be generalized or may be localized to the spinal column. Demineralization occurs when there is generalized involvement of the marrow without the formation of discrete tumefactions or plasmacytomas. The myeloma tissue thins the cortex and reduces the trabeculae in both thickness and number. Vertebral body collapse is often encountered. The presence of an associated soft-tissue mass adjacent to the spinal column favors myeloma over metastasis, but it does not rule out lymphoma.

Myeloma may, like metastatic hypernephroma and thyroid carcinoma, cause large areas of bone destruction with no sclerosis, especially in the pelvis. In the sacrum this change may be difficult to see, because of thinness of the bone and overlying gas.

Fig. 8—(A) Anteroposterior and (B) lateral views of the knee of a boy with hemophilia. The epiphyses are abnormally large and radiolucent. On the original roentgenograms, deposits of hemosiderin were evident in the soft tissues around the joint.

Continued

Lymphoma

Primary lymphoma of bone has come to be recognized as a real although uncommon entity which afflicts patients usually in the third to fifth decades. The lesions, which have a predilection for the long bones, typically start at the end of the bone. They often progress to involve a long segment of the shaft. The roentgen appearance is usually not diagnostic, although it almost always suggests the presence of a malignant bone tumor. Characteristically there is extensive disruption of the bony architecture, frequently with a mixture of lysis and sclerosis that results in a moth-eaten appearance. There is usually no periosteal reaction. An associated soft-tissue mass is common and, when present, aids in arriving at the correct diagnosis. The soft-tissue mass may contain calcification. Occasionally, lymphoma will involve bones on both sides of a joint. This may

rarely occur in myeloma and in infection. Other lesions that must be distinguished are osteogenic sarcoma, Ewing's sarcoma, and metastasis. Secondary deposits of lymphoma in bone may be either osteolytic or osteoblastic, and there is nothing about their roentgen appearance that helps in identifying them as lymphoma.

Hemophilia

Hemophilia and Christmas disease are the only bleeding diatheses that commonly cause bleeding of significant degree into bones and joints. Classic hemophilia is more common and more serious than Christmas disease, and it manifests itself most often as joint hemorrhage and occasionally as bleeding into bone itself. The arthritic changes will be considered first. The knee is most often involved, followed in order of frequency by the elbow and the ankle; the shoulder, hip, and wrist

Fig. 9—(A) Anteroposterior and (B) lateral views of the femoral shaft of a patient with hemophilia. There are cortical destruction, new bone formation, and a large soft-tissue mass; hemophilic pseudotumor. (From Ghormley, R. K., and Clegg, R. S.: Bone and Joint Changes in Hemophilia: With Report of Cases of So-called Hemophilic Pseudotumor. *J Bone Joint Surg [Amer]* 30A:589, 1948. By permission of the Journal of Bone and Joint Surgery.)

joints are uncommonly affected. The early stages of hemophilic arthropathy are probably no different from nonhemophilic hemarthrosis. The roentgenologic appearance is of increased density of the periarticular soft tissues and distention of the joint space. After repeated hemorrhages the blood that remains causes a chronic synovitis in which villous hyperplasia of the synovium develops and subsynovial fibrous tissue is laid down. The periarticular soft tissues become thickened, and hemosiderin is deposited in and around the joint; this may be detectable roentgenologically. The attendant hyperemia causes osteoporosis of the surrounding bone, and this may be a striking

Fig. 10—Gaucher's disease with so-called Erlenmeyer-flask deformity of the distal part of the femur. The cortex is thinned, and the medullary cavity is rather radiolucent. (From Pugh, D. G.: *Roentgenologic Diagnosis of Diseases of Bones*, Baltimore, Williams & Wilkins Company, 1951, p. 479. By permission of Williams & Wilkins Company.)

feature. Hyperemia may also cause enlargement and accelerated maturation of the epiphyses with premature fusion (Figure 8). These changes are best appreciated by comparing the affected joint with its unaffected mate. Juvenile rheumatoid arthritis and tuberculous arthritis also cause accelerated epiphyseal growth and maturation, presumably by the same mechanism. A finding, not unique to hemophilia but characteristic of the disease, is widening of the intercondylar notch. This is probably caused by erosion of the bone that is not protected by cartilage.

As a result of encroachment by the hypertrophied synovium, erosion of the articular cartilage occurs (starting at the margins), and there is narrowing of the joint space. Cysts commonly develop in affected joints. These cysts are irregular in both size and distribution, and although subchondral bone cysts are seen in other arthropathies, they are rarely seen in such profusion and with so much variation in size in nonhemophilic arthritides. Whether these cysts are due to hemorrhage into subchondral bone or to degenerative changes in the subchondral bone, as in osteoarthritis, is a moot point. It may well be that both mechanisms obtain. In time, osteophytes form, especially in weight-bearing joints.

Bleeding into bone is much less frequent, but it is often more dangerous than joint bleeding. The hemorrhage may be self-limited and of little significance, or it may be severe enough to kill the patient. When subperiosteal hemorrhage occurs, it usually behaves in the same way as hemorrhage from other causes: the hematoma calcifies, periosteal new bone is laid down, and eventually resorption occurs. In some instances, however, sufficient pressure builds up in the hematoma to erode the underlying cortex, and this, together with the hematoma calcification and periosteal new bone formation where the periosteum is elevated from the cortex, may simulate a malignant tumor, as Ghormley and Clegg⁹ have shown. This lesion, which has been referred to as "hemophilic pseudotumor," is usually found in the femur (Figure 9). Occasionally, when bleeding is into the epiphysis of a weight-bearing joint such as the hip, collapse of the epiphysis may result.

Gaucher's Disease

Gaucher's disease is a reticulosis in which cerebroside are accumulated in the reticuloendothelial system. The affected cells (Gaucher cells) are

Continued

present in the spleen, liver, lymph nodes, bone marrow, and occasionally in other organs. Although most afflicted persons are Jewish, apparently no race is immune. Approximately 70% of patients with Gaucher's disease have bone changes.

The earliest discernible roentgenologic change is a generalized demineralization of the distal part of the femora, with destruction of the spongiosa, due to proliferation of the Gaucher cells. As the disease progresses, the normal concavity of the medial side of the distal portion of the femur is lost, and eventually the border becomes convex. The same change occurs, albeit later, along the lateral border. The femur with advanced changes has been likened to an Erlenmeyer flask (Figure 10). This appearance is not pathognomonic of Gaucher's disease, for it is found in other conditions in which abnormal cells replace the bone marrow and encroach on the cortex. The ends of other long bones may be similarly demineralized and swollen, but usually less strikingly. The

changes are not limited to the metaphyses; the entire shaft may show thinning of the cortex and destruction of trabeculae. The cortex may be scalloped internally or it may be expanded, and the affected medullary regions may show homogeneous rarefaction or they may be coarsely reticulated. Sclerosis is an important feature of Gaucher's disease. This may be a result of a reparative process secondary to the destruction caused by infiltration of the Gaucher cells, although this is not an established fact. A common complication is collapse of the femoral heads as a result of infiltration by the Gaucher cells. The appearance of the collapsed head itself is no different from that in which the collapse is due to other causes, such as sickle-cell disease, caisson disease, cortisonism, and idiopathic avascular necrosis, although the appearance of the femoral shaft may provide a clue to the diagnosis. Occasionally, collapse of the humeral head and of vertebral bodies occurs by the same mechanism.

I Wanted to Be of Use in The World

In my childhood, doctors always seemed to me the highest type of human beings. They of all people, I thought, must be thoroughly good and constructive: their lives were dedicated to helping human life and comfort. I idolized my two brothers who were doctors, and the old physicians in Lynchburg whom I knew won my devoted respect. Doctor Dulaney and Doctor Latham and every other doctor were living forms of kindness; it seemed to emanate from their eyes, their fingers and their smiles. Knowing these men, I could not ever imagine that there could exist medical men who would quibble over fees, or chase ambulances, or go out to play golf after they had operated on a patient. These old doctors, despite the lack of our modern knowledge, brought profoundly healing self-sacrifice to their work. From the first day that I thought seriously about studying medicine, I held the profession in the highest idealism. To sign over one's life to the dedication of human needs: there could be no finer life to live!

Rosalie Morton (1876-) in *Why We Became Doctors*, edited by Noah Fabricant, 1954.

Untoward Reactions Associated with Antimicrobial Therapy

Part I. Cardiovascular, Respiratory,
Gastrointestinal, Hematopoietic, and
Genitourinary Reactions

ALTHOUGH ANTIMICROBIAL drugs have a welcome and salutary effect on many human infections, they often represent a double-edged sword by producing undesirable effects on the host. Some of the untoward reactions after treatment with these drugs are predictable, in the sense that a given ill effect is known to have an expected rate of occurrence. Contrariwise, other undesirable effects appear to be of increased incidence in certain predisposed subjects and are idiosyncratic and consequently often unpredictable. The purpose of this paper is to outline some of the untoward reactions that may occur after administration of the antimicrobial drugs in common use. An attempt will be made to categorize these reactions according to the various bodily systems or areas involved. Members of our group¹⁻⁷ and others⁸⁻¹³ have periodically reviewed this subject.

Cardiovascular

Pericarditis is a rare manifestation of allergy to a penicillin, and it has occurred also after the use of streptomycin or a tetracycline.

Antibiotic-induced changes in the microflora of the host may contribute to the occurrence of *endocarditis* in postcardiotomy patients, especially when such pathogens as *Candida* or diphtheroids are responsible.

Cardiac arrest may result from the potential curariform action of such drugs as streptomycin, dihydrostreptomycin, neomycin, kanamycin, polymyxin B (Aerosporin), and colistin (Coly-Mycin). Such an effect has occurred on intracavitary instillation of these drugs and should be

considered when they are given intramuscularly or intravenously to certain predisposed patients, as will be noted later. Administration of amphotericin B has resulted in cardiac arrest and arrhythmias including ventricular fibrillation.

Anaphylactic reactions may produce almost all types of cardiac arrhythmias, including various forms of heart block. Whether the reaction contributes to the production of actual myocardial infarction is debatable.

Diffuse vasculitis may be a rare manifestation of penicillin hypersensitivity. Like a number of other drugs, the penicillins appear to precipitate disseminated lupus erythematosus. Use of a sulfonamide also seems to precipitate lupus erythematosus and to result in periarteritis nodosa.

Intravenously administered antibiotics that are commonly responsible for chemical thrombophlebitis at the site of administration include amphotericin B, vancomycin (Vancocin), nafcillin (Unipen), the tetracyclines, ristocetin (Spon-tin), erythromycin, and cephalothin (Keflin). Solutions of sulfonamide salts for parenteral administration, such as sodium sulfadiazine and sulfoxazole, are highly alkaline and irritating to the tissues; if they are permitted to leak from a vein, necrosis of the tissues with sloughing may result. Frequent and repeated intravenous injections of these sulfonamides are not recommended because they tend to produce thrombosis of the veins. Due to the possibility of inducing chemical phlebitis, use of leg veins for introduction of these and other antimicrobial drugs is to be avoided.

In patients with cardiac disease one should be

Continued

aware of the increased intake of sodium on use of such antimicrobial drugs as methicillin, cephalothin, or a parenterally administered sulfonamide. Likewise, one should be aware of the potassium content in penicillin G given to these patients.

A "typhoid shock" syndrome after administration of chloramphenicol (Chloromycetin) to patients with typhoid fever is presumed to be due to excessive release of endotoxin and is similar to so-called bacteremic shock due to other gram-negative bacilli. Hypotension, of course, may be part of an anaphylactic reaction to almost any antimicrobial drug, but may present as an apparently isolated reaction to certain drugs, such as nitrofurantoin (Furadantin) and amphotericin B.

Peripheral vascular collapse may occur as a manifestation of the "gray syndrome," which has been noted in infants treated with chloramphenicol.

Respiratory

Among the manifestations of a reaction of the anaphylactic type, there may occur asthmatic respiration and various degrees of edema, including that of the larynx. The respiratory difficulty may become progressively severe until the subject is entirely preoccupied with breathing. He may recover slowly in the ensuing few minutes, or he may die in convulsions, literally gasping for breath. It is worth noting that in man there is no one dominant "shock organ" involved in anaphylaxis, and bronchospasm is not invariable.

On occasion, certain antimicrobial agents, especially the penicillins and nitrofurantoin, precipitate an isolated episode of asthma.

Use of a penicillin, erythromycin, novobiocin (Albamycin), lincomycin (Lincocin), cephalothin, and other drugs may depress the coccal members of the body flora and encourage superinfection in the form of pneumonia, due to overgrowth of such resistant organisms as *Klebsiella*, *Aerobacter*, *Pseudomonas*, and *Candida*. Periodic examination of the sputum and stools may allow detection of changes in the body flora in time to avert clinical superinfection. Contrariwise, administration of streptomycin, kanamycin, the tetracyclines, and other drugs may depress the gram-negative elements of the normal flora and allow the development of pneumonia because of the overgrowth of resistant staphylococci. Of course, superinfection is not limited to the respira-

tory tree, but can result in enterocolitis, bacteremia, pyelonephritis, and so forth. The phenomenon of superinfection due to antimicrobial-induced changes in the bacterial flora may be noted as early as the fourth or fifth day after therapy is initiated. Cessation of therapy responsible for a change in the bacterial flora is usually followed by a return to a normal flora within days, but in certain patients with diseases characterized by lowered general resistance, such may not occur for several weeks. In general, subjects most susceptible to superinfection appear to be infants, persons with underlying pulmonary disease, patients having a defect in immunizing capacity, and those receiving prolonged, intensive, or combined antimicrobial therapy. Strains of staphylococci, gram-negative bacilli, and yeasts appear to be the most commonly encountered organisms in systemic or visceral superinfections.

Superinfection, especially that due to *Pseudomonas* organisms, may complicate "mist therapy" that employs tap water as a vehicle. Similar infection may occur after tracheostomy because of the presence of "water bacilli" in various fluids and on medical instruments exposed to fluids. As previously noted, superinfection due to these organisms is abetted if the patient is receiving a drug, such as a penicillin, to which these bacilli are resistant; the bacilli are thereby relieved of the tendency to natural eradication by their normal microbial antagonists contained in the bodily flora.

Respiratory arrest may occur after use of the antimicrobial drugs that have a potential curariform action, such as streptomycin, kanamycin, neomycin, polymyxin B, and colistin. As noted in the case of cardiac arrest, a curariform effect is most likely to occur on intracavitary instillation of such drugs; however, intravenous administration of polymyxin B has caused respiratory arrest.¹⁴ Instillation of more than 2 mg. of streptomycin, more than 1 mg. of kanamycin or neomycin, or more than 0.5 mg. of polymyxin B or colistin per kg. of body weight into the pleural or other cavity of the narcotized, anesthetized patient is to be avoided. In the surgical patient, aspiration of the bulk of the solution containing one of these drugs at the end of the operation reduces the hazard of apnea or respiratory distress. Of course, under these circumstances, respiratory arrest is not central in origin but reflects neuromuscular blockade.

When, on occasion, certain antimicrobial drugs are administered as an aerosol, in some subjects the procedure may result in irritation of the bronchial tree. The resulting chemical bronchitis may produce findings that can be confused with those of the underlying respiratory condition.

Intrapleural instillation of various antimicrobial agents may also result in an untoward reaction in the form of chemical irritation. Such a reaction in some cases appears to represent host peculiarity. However, it is generally recommended that one avoid instilling certain drugs, such as the tetracyclines, into the pleural or other body cavity because of their irritating properties.

Pleuropneumonitis may represent an allergic reaction to nitrofurantoin and may be mistaken for other entities. Widespread crepitant or subcrepitant rales may be noted, and roentgenograms of the thorax may be clear or may reveal patchy infiltrations at the bases of the lungs. In patients with organic heart disease, these findings may be interpreted as manifesting pulmonary edema and cardiac failure. Chills, fever, cough, and dyspnea may be suggestive of pneumonia. Eosinophilia is frequent but not characteristic of eosinophilic pneumonitis, and the infiltrates are transient but not migratory.

The observation has been made that nalidixic acid (NegGram) may be capable of decreasing ventilation in patients with respiratory deficit.

Respiratory distress and cyanosis are among the manifestations of the "gray syndrome" which may follow the administration of chloramphenicol to infants. Respiratory distress and cyanosis are also among the multiple untoward reactions that may complicate therapy with amphotericin B.

Gastrointestinal

Glossitis and stomatitis may follow the use of certain antimicrobial drugs, including a penicillin, streptomycin, tetracycline, chloramphenicol, and lincomycin. A tetracycline given to the mother in late pregnancy or to the child during infancy or early childhood may cause subsequent discoloration of the child's teeth.

Any antibacterial agent given orally may cause gastrointestinal irritation, apparently reflecting its chemical nature and the individual's tolerance. The tetracyclines, the semisynthetic antistaphylococcal penicillins, lincomycin, nitrofurantoin, and

the sulfonamides not uncommonly generate such distress. Untoward reactions of this type include anorexia, belching, pyrosis, nausea, vomiting, abdominal cramps, and diarrhea. In this regard, loose stools are noted in about 15% of patients receiving lincomycin by the oral route, and diarrhea has required discontinuation of therapy in 2 to 3%. As a further example, gastrointestinal disturbances after oral administration of nitrofurantoin require discontinuation of its use in about 5% of cases. Of course, when frank diarrhea develops in a patient receiving certain predisposing drugs, a specimen of stool should be examined by smear and culture in an attempt to detect staphylococci. The potentially ominous significance of staphylococcal enterocolitis complicating treatment with tetracyclines, as well as with other agents such as streptomycin and the sulfonamides capable of depressing the normal gram-negative elements of the gastrointestinal flora, is well known. Such superinfection will be elaborated on in a paragraph to follow dealing with the effects of antimicrobial drugs on the normal flora of the gastrointestinal tract. Pruritus ani is particularly likely to be precipitated by oral use of a tetracycline. Proctitis may occur after therapy with a tetracycline, as well as with other drugs, including lincomycin.

Certain antimicrobial drugs, such as the semisynthetic antistaphylococcal penicillins, are not well absorbed after oral administration unless the stomach is otherwise empty. Food interferes with the absorption of these drugs, and consequently the decreased levels in serum may be insufficient to eradicate an infection. In this regard, although penicillin V and phenethicillin are said to be interchangeable for clinical use, the potassium salt of penicillin V has the advantage that its absorption is not similarly reduced.^{15,16}

An untoward reaction to penicillin G rarely has taken the form of hematemesis apparently due to an urticaria-like reaction of the gastric mucosa. Cases of bleeding from the gastrointestinal tract have occurred after ingestion of nalidixic acid. Hemorrhagic gastroenteritis is one of the complications of therapy with amphotericin B. Of course, many of the antimicrobial agents, especially those given orally, may prove sufficiently irritating to provoke an exacerbation of a peptic ulcer, with consequent gastrointestinal bleeding.

Continued

Neomycin administered orally in maximal daily doses may produce malabsorptive effects resembling those found in nontropical sprue. These effects include steatorrhea, azotorrhea, and interference with the absorption of vitamins, sugars, and minerals.

A serious biologic complication of antibacterial therapy in the gastrointestinal tract is the overgrowth of resistant organisms. As intimated under respiratory reactions, the microbial etiology of superinfection depends on the antibacterial spectrum of the agent employed, the endogenous flora of the host, and the organisms indigenous to a given environment. As previously noted, the administration of certain antimicrobial drugs, such as one of the tetracyclines, particularly to postoperative patients, may be associated with enterocolitis due to superinfection with coagulase-positive *Staphylococcus aureus*. This serious complication is not limited to surgical patients, but this is the most common clinical setting. Theoretically, oral use of predisposing antimicrobial drugs, rather than parenteral use, is more likely to cause staphylococcal enterocolitis, since it is difficult to build up a high concentration of an agent in the bowel on parenteral administration. Also, the better an agent is absorbed from the bowel, the less should remain therein to affect the flora, and hence the less the likelihood of staphylococcal superinfection; but again this is theoretic. Among the antibacterials depressing the gram-negative flora and predisposing to staphylococcal enterocolitis are the sulfonamides, streptomycin, neomycin, kanamycin, the tetracyclines, chloramphenicol, polymyxin B, and colistin.

Of course, superinfection is not limited to the intestinal tract and, as aforementioned, may result in pneumonia, bacteremia, pyelonephritis, and so forth. In addition to resistant staphylococci, overgrowth of gram-negative bacilli may occur after administration of a penicillin or an allied drug. Although use of one of the latter drugs may eliminate the coccal elements of the intestinal flora, the overgrowth of the gram-negative bacillary elements usually is not associated with clinical manifestations of an enteric nature. Superinfections with gram-negative rods are frequently due to *Escherichia coli*, *Aerobacter aerogenes*, *Proteus*, and *Pseudomonas*. In some patients, it may be difficult to ascertain whether these gram-negative organisms actually represent superinfec-

tion or whether they were present but masked in the initial infection.

In addition to bacterial superinfections, systemic dissemination of *Candida* may occur.¹⁷ Important diagnostic features may include the development of confusion or coma and hypotension associated with leukocytosis in patients receiving antimicrobial drugs, particularly in combination with adrenocortical steroids or antineoplastic agents.

Theoretically, at least, alterations in the bodily flora associated with the administration of antimicrobial drugs may represent a loss of bacterial function. As an example of this, synthesis of vitamin K, normally a function of the flora of the bowel, may be decreased when the flora is altered by antimicrobial therapy. Therefore, anticoagulants may be relatively more potent, and loss of control of coagulation may ensue with the previously correct dosage of the anticoagulant.

There are indications that administration of a tetracycline, especially intravenously, may interfere with coagulation of blood, via mechanisms other than alteration of the synthesis of vitamin K by the bacterial flora. This effect appears most likely to occur in patients who have had a bleeding tendency. Increased clotting time, decrease in plasma prothrombin activity, inhibition of prothrombin consumption, and retardation of thromboplastin generation are among the defects that may occur. In some of these patients, tetracycline-induced hepatotoxicity may be responsible for faulty coagulation.

The tetracycline group of antibiotics is concentrated in the liver, and these drugs have demonstrated their capability of producing fatty infiltration in the liver of experimental animals and of man.^{2,5,9} In 1951, Lepper reported fatal hepatotoxicity in human subjects after intravenous administration of large doses of a tetracycline. Hepatotoxicity after administration of a tetracycline in usual dosages has been observed during pregnancy, and the use of these drugs should be avoided in pregnant women unless their use is virtually mandatory. In keeping with the available data, it would seem advantageous to utilize the tetracyclines cautiously in patients with underlying liver disease. Other possible factors enhancing the likelihood of a hepatotoxic reaction include a daily dose in excess of 2 Gm., prolonged therapy, associated renal disease (which may result in serum accumulation of the drug),

and concurrent exposure to other hepatotoxic agents. In subjects who are predisposed to tetracycline-induced hepatotoxicity, one should monitor the blood levels; one should lower the dose if the serum concentration of the tetracycline exceeds 15 $\mu\text{g/ml}$. Patients suffering hepatotoxic reaction have had jaundice, azotemia, acidosis, hypocalcemia, prolonged prothrombin time, hemorrhagic diathesis including gastrointestinal bleeding, hypotension, and coma; autopsy may reveal extensive fatty changes in the liver.

Jaundice has occurred after use of erythromycin estolate (Ilosone). Robinson¹⁸ noted that in his series of patients receiving the estolate salt, 3.3% became jaundiced. Hepatotoxicity generally reflects one or two weeks of continuous therapy or several courses of the drug. The jaundice, usually a manifestation of intrahepatic cholestasis, subsides rapidly when use of the drug is stopped but reappears promptly if the drug is readministered, usually within 48 hours. Erythromycin, which is not hepatotoxic in its basic form, probably acquires this capacity by esterification of a side chain, that is, when a simple hydroxyl group is replaced by the propionyl radical.

Alterations in hepatic function have occurred in some patients after two weeks or more of therapy with triacetyloleandomycin (Cyclamycin, TAO) in a daily dose of 1 Gm.¹⁸ The abnormal reactions subside after use of the drug is discontinued.

In patients receiving novobiocin, scleral discoloration more often reflects the transient deposition of a harmless pigment produced by the metabolism of novobiocin, rather than hyperbilirubinemia.¹⁹ The yellow pigment has been found in the plasma of patients receiving the drug, and its presence may interfere with determinations of serum bilirubin and the icteric index. In young children, however, novobiocin may interfere with the conjugation of bilirubin and has caused hyperbilirubinemia. When scleral discoloration appears during therapy, administration of the drug should be discontinued until the nature of the pigment can be ascertained. Pigmentation

resulting from the metabolite of novobiocin, as distinguished from that of true jaundice, does not contraindicate continued use of the drug. Because of the possibility of novobiocin-induced hyperbilirubinemia, administration of novobiocin to newborn and young infants should be avoided.

Abnormal results of liver function have occurred in patients receiving lincomycin, but whether jaundice has resulted solely as a consequence of administration of the drug is uncertain.

The sulfonamides appear to have been hepatotoxic, and in the newborn, these drugs may actively compete with bilirubin for protein binding. A substance competing with bilirubin for binding may release the pigment, and this mechanism may be utilized in cases of sulfonamide-induced kernicterus.

Amphotericin B has precipitated acute hepatic failure. On rare occasions, nitrofurantoin and nalidixic acid appear to be hepatotoxic. Whether colistin is hepatotoxic remains uncertain.

Certain drugs including oxacillin, cloxacillin, ampicillin, cephalothin, and nalidixic acid may cause increased serum glutamic oxaloacetic transaminase activity, but it is the consensus that as an isolated finding, this does not necessarily reflect hepatotoxicity.

Administration of chloramphenicol to infants should be discontinued promptly if anorexia, abdominal distention, lethargy, and hypothermia develop. This "gray syndrome," which was alluded to previously, appears to reflect excessive concentration of chloramphenicol in the blood and is the basis for recommending that the drug be given to infants only in those rare instances when its use is imperative. A low level of glucuronyl transferase enzyme activity in the livers of newborn infants has been demonstrated. This enzyme, which is responsible for glucuronide conjugation of bilirubin, increases to normal levels of activity in the first two to three weeks of life. The glucuronide-conjugating mechanism appears necessary for the detoxification of chloramphenicol, and when the enzyme system is immature, it is hypothesized that the "gray syndrome" results.

Examination

You must look into people as well as at them.—Lord Chesterfield

Business is business.

Says who?

Says too many people.

You've probably heard it yourself many times.
It's used to justify almost *anything*.

But how many times have you ever questioned this attitude or raised your voice in protest? An idea like this takes root just because not enough people do anything to stop it.

If you have ever asked yourself "Why doesn't someone do something about it?" you're talking to the right person. You.

It won't be easy. Sometimes you'll need encouragement. The kind you'll find in your place of worship.

Here you'll discover you're not alone. That, in itself, can give you the strength to say "Says who?" once in a while when it needs to be said.

Grand Rounds

Thyrotoxic Heart Disease*

STEPHEN WEISBERG, M.D.
Medical Resident

History

In 1931-1932 Lahey called attention to a clinical variety of hyperthyroidism characterized by apathy rather than hyperactivity, to which he gave the name "apathetic thyroidism."^{1,2,3} Few cases of this entity are described in the literature, but textbooks either fail to mention "apathetic thyroidism" or dismiss it briefly.⁴

In 1930 Hamburger and Lev described thyroid toxicity which was "masked": " - - - men and women at or near the middle decade of life—individuals without exophthalmos, struma or tachycardia, apathetic, listless, with masked facies, dulled eyes, quiet and insensitive, in striking contrast to the alert, restless, nervous, bright, prominent-eyed patient with 'typical' hyperthyroidism."⁵

In discussing the atypical form of hyperthyroidism and its manifestations, it is of interest to trace the history of the description of this disorder. We have touched on the first descriptions of the "masked" form with which we are primarily concerned; but we will also discuss the more common form of hyperthyroidism and related cardiac dysfunction.

Caleb Parry in 1786 described the association of heart disease and enlargement of the thyroid gland.^{6,7,8} In the latter half of the 1830s, Graves and Basedow both described the association of cardiovascular symptoms and exophthalmic goiter.⁶

Trousseau in 1863, by his error of giving tincture of iodine instead of tincture of digitalis to a patient suffering from cardiac failure, established in retrospect the true cause-and-effect relationship of hyperthyroidism on cardiac function.⁶ He stopped the iodine upon discovering the error; nevertheless, the cardiac failure worsened. The clinical importance of iodine was not recognized for another sixty years.⁶

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, Minneapolis, October 4, 1966.

Continued

In 1923 Hamilton, in a review, showed that partial or complete relief of symptoms could be achieved in a large number of patients by thyroidectomy.⁹

Clinical Description

Masked hyperthyroidism is that form of thyroid disease in which the overactive thyroid gland does not produce classic symptoms, but manifests itself by symptoms restricted to a single system.¹⁰ The mono-symptomatic form is described in which disturbances of one system are prominent and suggest disease of that system.⁴ In the older age group the most common form of masked hyperthyroidism presents as cardiovascular disease, either atrial fibrillation, angina pectoris, or congestive heart failure. Of these, the most common is atrial fibrillation.¹⁰

Cases are described where some or most of the so-called classic features of hyperthyroidism are absent.⁴ An important group are those cases where the thyrotoxic signs are not truly atypical but are overshadowed by prominent signs of some other coincidental disease or symptom complex.⁴

Apathy represents a specific, though rather uncommon, response to the hyperthyroid state.⁴ Clinical manifestations include lethargy, placid facies, depressed mood, mental and physical inertia and thus, in general, the opposite of the usual hyperkinetic state.¹¹ Although not limited to the following groups, apathy usually is seen more frequently in the elderly, in patients without goiters or with small nodular goiters, and in patients with prominent cardiovascular symptoms.⁴

Incidence

A large series of 200 thyrotoxic patients revealed 30 per cent as having some cardiac abnormality.¹² This study indicated age to be the main factor in the production of the cardiac disease. The older patients were also found to have a greater incidence of nodular goiter and gave a history of longer duration of symptoms. In 14 per cent of their cases, thyrotoxicosis appeared to be the only cause of the heart disease. The prognosis with regard to mortality, morbidity, and reversion of atrial fibrillation to sinus rhythm was good in this group. The worst prognostic group included those with associated ischemic heart disease. Sandler and Wilson in a study and review of the nature and prognosis of heart disease in thyrotoxicosis show somewhat similar findings in a larger group of patients.¹³

Table 1 presents the analysis of 462 patients with thyrotoxicosis. Forty-three per cent are included in Group III, in which hyperthyroidism was the only known cause of the heart disease.

The progressive increase in incidence of heart disease in thyrotoxicosis with advancing age is well documented.^{12,13} The age distribution was similar in patients with and without associated heart disease.¹³ The female:male ratio in patients with cardiac involvement was 3.4:1; and 4.0:1 in the whole group was close to that in the thyrotoxic patients without cardiac complications.¹³

The incidence of nodular goiter did not appear to be related to the development of cardiac complications.

The incidence of atrial fibrillation and congestive heart failure increased with age, with atrial fibrillation the most important factor in producing congestive heart failure. The prognosis of patients with congestive heart failure is shown in Table 2.¹³ The severity and duration of the thyrotoxic state was not felt to be significant in producing cardiac complications.^{13,14}

Pathology

Schlesinger and Benchimol reported the pathology in four cases of thyrotoxic heart disease in which cardiac involvement was attributed solely to hyperthyroidism in the absence of any other etiologic factor.¹⁵ The rarity of the disorder does not allow for extensive discussion of pathologic findings. Of the author's four cases, three manifested cardiac failure. One patient with heart failure revealed dissociation of myocardial fibers and interstitial edema at autopsy. Cardiac hypertrophy, primarily left ventricular, was found in the fourth patient who had remained compensated prior to death. Changes of serous myocarditis have been described in cases with the pure form of thyrotoxic heart disease.¹⁴

The importance of recognition of the thyrotoxic patient with cardiac dysfunction is that the pure form will respond to appropriate medication. The more chronic and less responsive patients are those in whom underlying organic heart disease already exists. In the latter case, the hemodynamic changes affect a previously damaged heart. Schlesinger and Benchimol feel that heart failure in the pure form is due solely to effects of thyroid hormone on the heart muscle.¹⁴

TABLE 1*

Thyrotoxic patients treated with I 131, January, 1949 to October, 1956		462
Group I. Patients without cardiac involvement		312

Continued

Goodpasture in 1921 reported two cases of thyrotoxicosis associated with heart failure.¹⁶ He emphasized the pathologic findings of myocardial degeneration, infiltration, necrosis and fibrosis which were considered as specific effects of the thyroid hormone. He also obtained similar changes experimentally.¹⁷

Goodall and Rogers in 1927 and Lewis in 1932 observed a similar type of myocardial lesion in fatal cases of hyperthyroidism and concluded it was due to the direct influence of thyroid secretion on heart muscle.^{18,19}

In 1941 Duchosal and Henny reported the case of a thyrotoxic patient with angina pectoris who died suddenly following thyroidectomy.²⁰ At post-mortem examination the myocardium showed degeneration with areas of interstitial fibrosis but no coronary artery pathology.

In 1948 Lemos Torres described two patients who died from thyrotoxic crises. Autopsy revealed cardiac changes characterized by serous myocarditis with fibroblastic degeneration.¹⁴

Physiology

The physiologic alterations in the thyrotoxic state should help to explain the cardiovascular changes. Although the exact cause of myocardial hypertrophy is not known, it is obvious that circulatory states associated with increased cardiac output and/or vascular resistance result in myocardial hypertrophy. The cause of hypertrophy of the myocardium appears to be related to an increase in the mechanical work of the heart.²¹

Some of the circulatory changes in thyrotoxicosis are increased mean blood pressure in both the pulmonary and systemic circuits, an increased cardiac output and velocity of flow, and an increased pulse rate which is even beyond the increased metabolic requirements of the thyrotoxic state.^{22,23,24}

The findings of left-sided cardiac enlargement can then be explained on the basis of increased mean systemic blood pressure and increased cardiac output. The right-sided changes are not only influenced by the mean pulmonic pressure and cardiac output but may be greatly affected by flow rate.²¹

Cardiac catheterization studies demonstrate an increase in oxygen consumption, cardiac rate, cardiac output, left ventricular work, coronary blood flow, and cardiac oxygen utilization in patients with thyrotoxicosis.²⁵ After treatment, these authors found a decrease in these functions, while coronary vascular resistance increased. These findings are compatible with the works of others in that the coronary vascular response and myocardial metabolic changes are similar to those seen in other tissues in the presence of excessive thyroid hormone.²⁵

A direct alteration of myocardial function by thyroxin has been demonstrated in both clinical and experimental hyperthyroidism.²⁵ The failure of adequate cardiac output response to exercise has been thought to be due to altered enzyme function resulting in impaired myocardial energy production.²⁶ The action of thyroxin on myocardial function may well be mediated by sensitization of the myocardium to sympathetic nerve stimulation and to sympathomimetic amines.²⁷ An increased concentration of catecholamines has been demonstrated in the myocardium of thyrotoxic dogs.²⁸

A dose-response study of euthyroid* and hyperthyroid subjects to intravenous epinephrine demonstrated a greater reactivity of the thyrotoxic group. Differences in the magnitude of increases of oxygen consumption, blood pressure, and heart rate clearly separate the two groups.²⁹ The increased sensitivity to epinephrine was shown not to be due to hypermetabolism. Patients with diseases associated with increased metabolism but normal thyroid function react to epinephrine

*See Test Your Word Score Page 1359.

normally.²⁹ The level of circulating thyroid hormone is felt to be a major factor in determining the response to epinephrine administration.²⁹

Hyperthyroidism in both man and the experimental animal produces an increased susceptibility to cardiac arrhythmia after parenteral administration of epinephrine.³⁰ The frequent occurrence of atrial fibrillation in patients with thyrotoxicosis in the absence of organic heart disease has already been shown. Although atrial fibrillation does not compromise the circulation at rest, impaired circulatory responses to the increased demands of exercise are well documented.³¹ Since the circulation of the hyperthyroid patient is under a constantly increased load even at rest, the importance of this arrhythmia as a factor in the development of congestive failure is evident.³²

In addition to the direct alteration of myocardial function by excess thyroxin, the presence of an increased peripheral circulatory load in these patients is suggested by the occurrence of heart failure at absolute levels of cardiac output which were normal or high.³³ The hemodynamic data in these patients closely resembled in many important respects that obtained in patients with systemic arteriovenous fistulae.³³ The peripheral circulatory load in thyrotoxicosis is hemodynamically similar to that of systemic arteriovenous fistulae. An increase in blood volume is seen in both groups.³³ The continued development of hypervolemia, which initially represents a desirable circulatory adjustment, may well be a factor in the development of myocardial dysfunction because of an increased venous return, overdistention of the heart, and perhaps ultimately the development of atrial fibrillation.³⁴

The development of congestive heart failure may thus occur in thyrotoxicosis for a number of reasons. With inadequate myocardial function resulting from a direct effect of thyroxin on the heart in the presence of sympathomimetic amines and an associated increased circulatory load, the heart with pre-existing organic disease or even the normal heart may fail.³³

The similarities between the cardiovascular effects of excess thyroid hormone and epinephrine administration have stimulated an evaluation of the therapeutic effects of sympathetic blockade in hyperthyroidism. Spinal anesthesia has been shown to prevent hyperkinetic cardiovascular responses during thyroid surgery.³⁵ Drugs which inhibit sympathetic adrenergic functions are thus used clinically in thyrotoxicosis. Guanethidine is a potent adrenergic blocking agent which selectively blocks the reflex responses to sympathetic stimulation, inhibits the uptake of circulatory norepinephrine, enhances the action of injected catecholamines, releases norepinephrine from bound tissue stores, and causes a slow but continuous release of norepinephrine.³⁶ The mechanism responsible for the guanethidine response in thyrotoxicosis may be: Blockage of the effect of tonic sympathetic discharge on the heart; reduction in myocardial catechol content, or reduction of myocardial response to circulating catecholamines.³⁶ The authors demonstrated that parenteral administration of guanethidine returned the elevated heart rate, blood pressure, cardiac output and cardiac work towards normal.³⁶

Clinical Findings

Atrial Fibrillation

All patients with atrial fibrillation, particularly if they do not respond to orthodox therapy, should be suspected of hyperthyroidism. This is true even when a definite cardiac etiology is established. Hyperthyroidism has been reported as the etiologic agent in 3.5 to 14 percent of all cases of atrial fibrillation.¹⁰ Atrial fibrillation occurs in up to 90 percent of hyperthyroid patients.^{14,32,37} Atrial fibrillation in hyper-

Continued

thyroidism increases in incidence with age.

Ernstene reported 1,000 consecutive cases of thyrotoxicosis in which atrial fibrillation occurred in 207.³⁸ Seventy-five percent occurred in patients over the age of 45, although only 25 percent of the 1,000 cases were over this age. Approximately 150 of the 250 patients over the age of 45 fibrillated, an incidence of roughly 60 percent.

The implications of these studies are quite clear. All patients with atrial fibrillation should be studied to rule out thyrotoxicosis.

The reversibility of atrial fibrillation to normal sinus rhythm in patients with hyperthyroidism is of diagnostic, prognostic and therapeutic significance. In most instances in which hyperthyroidism is the only cause of atrial fibrillation, spontaneous reversion to normal sinus rhythm will often occur upon restoration of euthyroidism.³⁹

Angina Pectoris

Those cases with angina associated with thyrotoxicosis in which the precordial pain is not responsive to rest and vasodilator drugs, but which responds to anti-thyroid drugs are of interest. It is postulated the anginal syndrome results from myocardial anoxia due to the direct effects of thyroxin on the heart muscle.¹⁴

Laboratory Diagnosis

The diagnosis of masked hyperthyroidism must largely depend on laboratory methods since absence of classic clinical symptoms is characteristic of this condition.¹⁰

Basal metabolic rate determinations may not be accurate.¹⁰ Congestive heart failure, hypertension, orthopnea, pulmonary disease, and arteriovenous aneurysms may produce elevation of the test. Peripheral edema may in some cases reduce the value of the metabolic rate.

The circulation time is frequently increased in thyrotoxicosis; however, this is not always the case if heart failure exists. Increased circulation time is suggestive of hyperthyroidism if anemia, fever and vitamin B deficiencies have been excluded.¹⁰

The serum protein-bound iodine has been reported to be decreased, and thus in error, if patients have received mercurial diuretics.³⁹

Radioactive iodine uptake is not affected by non-thyroid cardiac disease or by any other extrathyroid factor which may affect other tests, except for certain medications.¹⁰

Radiologic aids are often important and helpful. Generalized cardiac enlargement may be a common radiologic finding in thyrotoxicosis and may be preceded by enlargement of the pulmonary artery.¹³ Prominence of the main pulmonary artery alone or in combination with a high or prominent aortic arch has been noted.²¹ Cardiac enlargement in the absence of congestive failure was unusual. When cardiac enlargement was present, the left ventricle was the predominant chamber.^{15,21,22} The roentgenographically abnormal patients showed a greater pulse rate and mean blood pressure than other patients with thyrotoxicosis.²¹

When electrocardiographic evidence of left ventricular hypertrophy exists with no radiologic evidence of enlargement, a return of the electrocardiogram to normal may occur after treatment.¹³ The presence of both radiologic and electrocardiographic changes represents a more severe and permanent form of cardiac damage which may not be reversible.¹³

Treatment

In patients with thyrotoxicosis it is often difficult to assess accurately or objectively the response to digitalis. As reported in a sizeable series of patients with congestive heart failure and/or atrial fibrillation associated with hyperthyroidism the therapeutic response was quite definite even before the euthyroid state was established.³⁹ The usual degree of slowing of the ventricular rate after digitalis administration is not noted in these patients. The dosage of digitalis is increased significantly in patients with hyperthyroidism.³⁹ Digitalis is clearly indicated and is beneficial in congestive heart failure accompanying hyperthyroidism. Ultimate correction of the metabolic burden of hyperthyroidism on the heart and circulation will, however, not be accomplished until the thyroid disorder is successfully controlled.³⁹

We have previously discussed the use of agents such as guanethidine. This drug is recommended in severe overt hyperthyroidism because of its potent and unique sympatholytic effects, thus ameliorating promptly and effectively those signs and symptoms of thyrotoxicosis due to sympathetic hyperactivity without affecting the function of the thyroid gland.⁴⁰ The dosage of guanethidine is usually 50 to 100 mgm. initially.⁴⁰ A single oral daily dose or divided doses orally or intramuscularly is recommended. Twenty-five mgm. increments every third day are given until a therapeutic end-point is reached. One observes complete control of signs and symptoms of the disease or distinct orthostatic hypotension. The dose at which an end-point is reached is then continued as maintenance. In Waldstein's series, a satisfactory response was achieved on the average by six days and not later than the second week of therapy.⁴⁰ Thus, like digitalis in some respects, guanethidine does not correct the basic hormonal disturbance; it can only be considered an adjunct to definitive therapy and recommended for short-term aid in the management of the thyrotoxic patient with severe heart failure.^{36,40}

The importance and need for agents such as propylthiouracil and methimazole are well known and require little explanation.

Thyroidectomy today in patients with heart disease is not the disastrous ordeal it was prior to the development of antithyroid medication. Goitrogenic therapy allows for subtotal thyroidectomy in selected patients. However, radioactive iodine in adequate doses is rapidly replacing surgical thyroidectomy because of its simplicity of administration, predictable effectiveness, paucity of complications and obviation of the need for hospitalization.³⁹

In one series, approximately one third of patients with atrial fibrillation reverted spontaneously to normal rhythm after radioactive iodine.¹³ More than one half of the patients with congestive failure had no further attacks of failure after radioactive iodine, and more than one third required no further treatment with digitalis.

The prognosis was adversely affected when atrial fibrillation was associated with congestive heart failure.¹³ The rate of reversion with radioactive iodine was higher in younger patients. The over-all prognosis was more favorable if sinus rhythm could be restored in patients with congestive heart failure and atrial fibrillation. Radioactive iodine therapy is safe and effective and is the treatment of choice in thyrotoxic patients with severe cardiac complications.¹³

Case Report

A 56-year-old white, widowed, female cleaning woman, was admitted for the first time to Hennepin County General Hospital on 7/12/66.

Two weeks prior to admission the patient noted the onset of progressive pedal edema which progressed to the sacral region. Accompanying the edema was dyspnea on exertion progressing to orthopnea and paroxysmal nocturnal dyspnea. The patient complained of palpitations. Also

Continued

noted were occasional bouts of low substernal chest pain.

The patient was seen by a private physician, who made a diagnosis of congestive heart failure, administered 2 cc. of thiomerin parenterally, and referred the patient for admission to this hospital.

Physical examination on admission revealed a woman appearing older than her stated age with apathetic facies, flattened affect, suggestion of a stare, and in moderate respiratory distress.

The blood pressure was 130/80, respirations 28, regular but labored, and the apical pulse irregular and approximately 150.

Marked distention of the neck veins with filling from below was noted. Examination of the chest revealed bilateral dullness at the bases with medium to coarse, moist rales. The left cardiac border was found to be in the mid-clavicular line, fifth intercostal space. A protodiastolic gallop was present. No murmurs were audible. A_2 equal to P_2 .

The liver was enlarged three fingerbreadths below the right subcostal margin and was tender. Questionable ascites was present. Pitting edema was present from the abdominal wall inferiorly to the feet bilaterally. No neurologic abnormality was noted. No tremor was present. The reflexes were only slightly hyperactive and equal.

Chest x-ray revealed bilateral pleural effusions with slight cardiac enlargement. Electrocardiograms revealed atrial fibrillation and right axis deviation.

Hemoglobin was 12.4 grams percent. Cholesterol was 150 mg. percent. Normal liver and renal function studies were obtained.

Hospital course (Figure 1): The patient was given 2 cc. of thiomerin parenterally on 7/12/66 and 7/14/66. A dose of Lanoxin of 3.0 mg. was administered orally over the next 24 hours. Maintenance of 0.25 mg. Lanoxin twice a day was increased on 7/18/66 to 0.5 mg. in the A.M. and 0.25 mg. in the afternoon orally. On 7/22/66 the dosage of Lanoxin was increased to 0.5 mg. orally twice a day through 8/5/66. The pulse rate did not fall below the range of 100 to 110 until the latter dose was started.

A diuresis of 16 pounds occurred within 48 hours and 24 pounds by the end of five days. A total loss of 37 pounds had occurred by the 23rd day.

On the 10th hospital day, the patient experienced sharp right-sided pleuritic chest pain. Clinical, radiological and laboratory studies confirmed the presence of a pulmonary infarct. The patient was treated with heparin with an excellent response.

A serum protein-bound iodine (PBI) drawn on 7/17/66 was 8.4 mcg. percent. A second PBI drawn on 7/26/66 was later reported as 10.4 mcg. percent. A third PBI drawn on 8/2/66 was 10.8 mcg. percent. On 8/4/66 a radioactive iodine uptake was performed and was 40.5 percent at 24 hours. However, the patient had an emesis shortly after receiving her iodine

Figure 1

dose and thus the uptake may have been inaccurate. A basal metabolic rate determination was +38 percent on 8/3/66.

Tapazole was begun on 8/6/66, at a dosage of 15 mg. orally every eight hours. Within 24 hours the dose of Lanoxin was halved because of the ventricular response and in five days only 0.25 mg. per day was required. On the sixth day of Tapazole, the patient's cardiac arrhythmia converted to a normal sinus rhythm. She had noticed marked symptomatic improvement in terms of mood elevation, less fatigue, increasing appetite and weight gain.

The patient was discharged three days after conversion to sinus rhythm and was seen in the Outpatient Department two weeks later. She had gained eight pounds and felt better than she had in some time. Lanoxin was discontinued and Tapazole was tapered over a three-month period.

The thyroid I¹³¹ uptake was repeated after stopping Tapazole for 10 days, three months after discharge from the hospital, and was 67 per cent at 24 hours. The patient was then treated with radioactive iodine.

Quick Work

Sodbuster doctors operated on threshers' mangled legs on a parlor sofa, the kitchen table, or the familiar door placed on saw-horses. They set fractured femurs with a piece of string and a flatiron. They executed podalic versions on the kitchen table. They still were men who brooked no delay. When Dr. William Mayo visited a Minnesota granger farm, he spoke to a small boy. The child replied with a twisted tongue.

"Why, that child is tongue-tied," exclaimed the doctor. "Come here, George!"

The boy climbed on his knee as Dr. Mayo took out a pair of scissors from his pocket case. The lad opened his mouth; the doctor snipped the membrane that bound his tongue. He gave the youngster an affectionate pat and sent him on his way. The boy used his untied tongue so well he grew up to be a judge.*

Health

There's lots of people in this world who spend so much time watching their health that they haven't the time to enjoy it.

—Josh Billings

She doesn't feel she "suffers" from hypertension

**Butiserpazide® lowers blood pressure
so smoothly that patients are often untroubled
by either disease *or* therapy**

By switching patients to BUTISERPAZIDE you may be able to free them of much of the burden of hypertension. Clinical comparisons have shown that many respond with (1) smooth, uniform lowering of blood pressure¹...at times to levels *below* those attained with previous therapy²; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness²; plus

(3) "...lowered incidence of drug side effects."²

And there's an added advantage: the usual dosage is just 1 tablet once or twice daily, often without need for supplementary therapy. (BUTISERPAZIDE provides not only hypotensive and diuretic action, but a mildly sedative effect as well.) Isn't this the way to take the suffering out of hypertension?

You have a choice of 2 strengths:

Butiserpazide®-25

Prestabs®* Tablets

in mild to moderate cases, often effective at half the usual thiazide or thiazide/reserpine dosage.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 25 mg. (¾ gr.); Reserpine 0.1 mg.

Butiserpazide®-50

Prestabs®* Tablets

controls many moderate to severe cases without any need for ganglionic blockers, or other more potent agents; if such agents are needed, their dosage can be cut in half.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 50 mg. (¾ gr.); Reserpine 0.1 mg.

*15 mg. of Butisol (butabarbital), plus the other ingredients, in outer layer; 15 mg. of Butisol (butabarbital) in a specially coated core for delayed action, to approximately equalize duration of action for all components.

Contraindicated in presence of renal impairment, peptic ulcer, ulcerative colitis, or mental depression, and in patients with porphyria or those sensitive to any component. **Warning:** Coated potassium tablets, sometimes administered in conjunction with anti-hypertensive therapy, may be associated with small bowel lesions which have led to obstruction hemorrhage, and perforation. Surgery has been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occur. **Precautions:** Exercise caution in hepatic disease, diabetes, surgery, coronary artery disease, epilepsy, E.S.T., and in patients receiving digitalis. **Side Effects:** Electrolyte imbalance, hyponatremia, hypochloremic alkalosis and/or hypokalemia, hyper-

uricemia and gout, bradycardia, drowsiness, skin rashes, hangover, systemic disturbances, weakness, leg cramps, diarrhea, epistaxis, dizziness, urticaria, dry itching skin, nausea, vomiting, palpitation, superficial skin bruises, headache, dehydration, paresthesias, photosensitivity, pancreatitis, jaundice, xanthopsia, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, nasal congestion, hypotension, lassitude, loose stools, anorexia, bizarre dreams, peptic ulcer, ulcerative colitis, mental depression. (Ammonium chloride, which may be administered to reverse hypochloremic alkalosis, should not be given to patients with hepatic disease.) **Before prescribing or administering, see package insert.** †Warning: May be habit forming. **Usual Adult Dosage:** Butiserpazide®-25 or Butiserpazide®-50: 1 tablet daily or b.i.d. **References:** 1. Johnson, H. J., Jr.: *Penna. M. J.*: 67:35, 1964. 2. Coodley, E. L.: *Curr. Ther. Res.* 4:460, 1962.

FORT WASHINGTON, PA.

Tissue's healing nicely. Yet anxiety slows his steps toward recovery.

By helping overcome anxiety and tension which can thwart the convalescent's progress, EQUANIL (meprobamate) often may play an important role in medical and surgical aftercare.

Cautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use may result in dependence or habituation in susceptible persons—as ex-addicts, alcoholics, severe psychoneurotics. After prolonged high dosage, drug should be withdrawn gradually to avoid possibly severe withdrawal reactions including epileptiform seizures. Side effects include drowsiness and, rarely, allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute non-thrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. If an allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Warn patients of possible reduced alcohol tolerance. Should drowsiness, ataxia, or visual disturbances occur, dose should be reduced. If symptoms persist, patients should not operate vehicles or dangerous machinery. A few cases of leucopenia, usually transient, have been reported following prolonged dosage. Other blood dyscrasias—aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia—have occurred rarely, almost always in the presence of known toxic agents. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. Prescribe very cautiously for patients with suicidal tendencies. Suicidal attempts should be treated with immediate gastric lavage and appropriate supportive therapy.

Contraindications: History of sensitivity to meprobamate.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

EASTERN WISCONSIN CLINIC in rapidly growing community of 50,000 desires board-eligible or certified physicians in obstetrics and gynecology, pediatrics, orthopedic surgery, urology and otolaryngology. Well-equipped clinic and excellent hospital facilities. Lake shore location offers ample recreational facilities. Attractive financial plan leading to early full partnership. Full expenses paid for applicants invited to interview. Call or write: F. L. Hildebrand, M.D., Riverside Clinic, Menasha, Wisconsin.

EXCELLENT OPPORTUNITY. Established General Practice, sixteen years. Country home, office, equipment available July 1. South Central Minnesota town 12,000. Specializing. Contact A. L. Ourada, M.D., Fairmont, Minnesota. Phone 235-5848.

OFFICE SPACE now available in busy Bloomington. 713 square feet of new space in building with busy group of G.P.'s, dentist and suburban OB-GYN office. Ideal for ophthalmology, ENT or pediatrics. 8040 Penn Avenue South. 888-9211.

WANTED: GP to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

GENERAL PRACTICE associate wanted for young three man group in populous growing area located 30 minutes south of the Twin Cities. Spacious three year old clinic with new accredited hospital and nursing home in same town. Salary and terms open. Contact River's Edge Medical Clinic, Farmington, Minnesota. Telephone 463-7181.

WANTED: General practitioner, to join two G.P.'s well established in north central Minnesota community, 2200 pop., 65 miles from Twin Cities. Excellent office space with lab and X-ray, just opened new hospital, all facilities. Assistantship or partnership. Considerable surgery and obstetrics. Hunting, fishing, golf club. Great opening for interested G.P. WRITE MINNESOTA MEDICINE—381; 375 Jackson, St. Paul, 55101.

DON'T OVERLOOK THIS . . . 3 month's rent free in modern medical clinic—successful location in N. W. suburb of Minneapolis. Come see anytime—36th and Noble Avenue North. Noble Drug, 588-9449, Ben or Lou.

10:45-11:30 Cerebral Edema and Benign Intracranial Hypertension Anna L. Ellington

Cerebrovascular Disease and Convulsive Disorders

Chairman: Fernando Torres

1:30- 2:00 Acute Completed Strokes Clark H. Millikan

2:00- 2:30 Internal Carotid Insufficiency William J. Riley

2:30- 3:00 Basilar Vertebral Insufficiency Arthur C. Klassen

3:15- 3:45 Grand Mal Seizures Fernando Torres

3:45- 4:15 Status Epilepticus David Daly

Law and Medicine

The Minnesota Hospitalization and Commitment Act

THE ACT closely resembles recent enactments in Alaska, Illinois, Michigan, Ohio, Pennsylvania and Texas, which are likewise designed to render access to treatment facilities easier for persons in need thereof, while maximally preserving civil rights and humane consideration of these persons.

Application

The Act explicitly applies to public and private hospitals and institutions,* unlike its predecessor, which applied only to state hospitals unless otherwise specified.** In the past, private and general hospitals often followed statutory provisions, such as having a patient sign an agreement to give three days notice of departure from the hospital, during which time personnel felt legally justified in holding him against his will. The hospitals and institutions were not protected at all by the statute, plainly inapplicable to such facilities.

Informal Admission Procedure

Section 3 will remove the requirement of present §525.75 that a psychiatric patient voluntarily entering a hospital sign a formal application. This facilitates admission of patients of borderline mentation whose written consent would be of doubtful legality. It also avoids frightening away from needed care individuals whose paranoid attitude makes them suspicious of signing a formal documents.

*Section 2, Subdivision 8.

**Minnesota Statutes Annotated §525.749, Subdivision 8.

†§525.751, Subdivision 2.

Emergency Hospitalization

The present law† providing for emergency detention on a physician's certificate, applies only in state hospitals. Section 4 Subdivision 1 of the new Act will allow admission or detention and emergency treatment of a person whom a licensed physician has examined within the last 15 days and whom he believes to be mentally ill and in imminent danger of causing injury to himself or others if not immediately restrained.

Restates Common Law

Probably in the absence of such a statutory provision detention under these conditions would not sustain a charge of false imprisonment against hospital and physician. Subdivisions 1 and 2 make such a physician's statement sufficient authority for a peace or health officer to transport the person to a hospital. (An officer probably has this authority at common law too.)

Protects Patient

This section is actually a limitation upon the emergency authority of physician and officer: the person may receive care no more extensive than covers the emergency condition; it must be an emergency such that a court order of commitment cannot be obtained in time to prevent injury; the physician's statement must be in writing. These requirements and the precise wording of the section should help to prevent abuse of the power granted.

Continued

Patient Protected from Being Railroaded

A person who becomes a patient by emergency hospitalization is to be discharged within 72 hours unless a petition for commitment has been filed within that time.

Right to Communicate

This is one of many provisions* protecting against the "railroading" of people into a mental hospital, which appears to be widely feared. A further protection lies in Section 5 Subdivision 1, which entitles the emergency patient to communicate with others outside the hospital and in particular entitles him to private consultation with his attorney and his private physician. The right to consult an attorney probably exists in the absence of statute for any person confined against his will. The right to consult a private physician is a creature of statute. Neither provision has its counterpart in existing Minnesota law; both further protect against "railroading."

The right to communicate with physicians and attorney will also be granted by Section 7 Subdivision 4 to those hospitalized on petition for judicial commitment. Additionally, it will be mandatory for the patient to be informed of this right in writing at the time of his admission.

Right To Be Discharged

Further protection against "railroading" is contained in Section 6 Subdivisions 1 and 2 of the new Act: every patient held under emergency hospitalization must be examined not more than 48 hours after admission. He will be entitled to be discharged as of right should the examination not be held or should the examiner fail to certify to the head of the hospital that the patient is mentally ill and in need of care, treatment and evaluation.

Habeas Corpus Assured

A writ of habeas corpus is the traditional challenge to an unlawful detention of the person. The patient's right to immediate discharge will be enforceable by the writ, specifically preserved in Section 21 Subdivision 3 of the new Act.

*Subdivisions 6 through 15 of Section 7 deal with procedural due process: notice, right to counsel, right to be heard and to present witness. The counterparts in the present law are in §525.751 Subdivisions 2 and 4.

Hearing Required Within 30 Days

A person detained by court order upon a petition of commitment must be granted a hearing within 30 days after filing the petition except for good cause shown, according to Section 7 Subdivision 8 of the new Act.

Abuse of Hold Order

§525.751 Subdivision 2 of the present law authorizes the court to order confinement of a person in a hospital or other place for observation and examination. Under this provision a number of people were confined in one state hospital indefinitely, the hospital administration apparently feeling bound to continue to execute the court order indefinitely, a concrete and probably erroneous interpretation of the order. Since the present law, unlike the new Act, does not require informing a patient of his rights, acceptance by these patients of their plight was understandable.

Under the new Act a patient falls under emergency hospitalization with its examination and certification required within 48 hours or falls under judicial commitment with hearing mandatory within 30 days. Since no isolated provision for a hold order exists under the new Act, abuse thereof cannot occur as happened under present law.

Judicial Commitment

In accordance with the new Act a petition initiating commitment proceedings may be filed by any interested person (under Section 7 Subdivision 1). Present law, nearly as broad, allows any relative or reputable resident to file a petition (§525.751 Subdivision 1).

Arbitrary Refusal of Petitions Curbed

Under the present law in Hennepin County the probate court commissioner's office rejected petitions filed by persons other than immediate family members, notwithstanding the broadness of the statutory provision. The new section makes filing of a petition by the probate court mandatory when the requirements of the section are met. This should discourage the arbitrary local practice described above.

Physician's Certificate Required

However, under the new Act, unlike under

present law, the petition must be accompanied by a physician's certificate stating that he has examined the proposed patient and that he believes the latter should be hospitalized or by a statement that such examination could not be obtained or could not be performed. This section is designed further to protect the patient from unnecessary commitment by a determination of need for hospitalization prior thereto.

In Hennepin County the rules of procedure for the probate court commissioner's office presently require before the filing of a petition a written recommendation by a licensed physician that psychiatric examination and evaluation are indicated. The purpose of this requirement is plainly preselection similar to Section 7 Subdivision 1 of the new Act, but the Hennepin County rule improperly obstructs the broad permissiveness of the present law as the legislature drafted it.

Psychologist May Be an Examiner

After filing of the petition, the court shall appoint two designated examiners to assess the patient's mental condition and report their findings to the court*, thereby tending to insure that the patient's mental condition will be assessed by at least one person skilled in psychiatric evaluation.

Humane Innovations

Accompanied by Interested Person

In addition to procedural due process the new sections provide some purely humane innovations. For example, Section 7 Subdivision 6 requires personal service of notice upon the patient to be effected by a person not in uniform. Notice may be omitted if the court believes it would be injurious to him, provided a guardian ad litem is appointed to receive notice for the patient.

Absent From Hearing

Subdivision 12 permits the patient to be absent from the hearing provided the hearing officer shall have observed and consulted with him previously. This provision is to spare the patient from a

traumatic experience. Presumably the decision to absent the patient from the hearing will be made upon the urging of counsel and psychiatrist; it is doubtful that the court will be as capable of distinguishing its own projected or empathic feelings for the patient from recognition that the hearing for many patients may be a corrective emotional experience promoting improved reality testing.

Protection From Drugging

Subdivision 12 requires that the patient not be so drugged or medicated as to be hampered in preparing or participating in the proceedings.

Misguided Administrative Zeal

Already in Hennepin County the probate court commissioner has required discontinuance of medication prior to the hearing except where absolutely necessary to control the patient. Such a requirement represents excessive administrative zeal: withdrawal of tranquilizing medication which is not so heavy as to obtund the patient permits return of psychotic symptoms which the medication often effectively eliminates. The return of the symptoms may be destructive to a patient. Presumably the value of the relapse would be to demonstrate to the court the patient's underlying, untreated condition. However, that is the function of the designated examiners and of the hospital staff who care for and observe the patient prior to the hearing. The language of the new statute is sufficiently clear to end this administrative fiat.

Avoiding a Constitutional Issue

Subdivision 12 also permits exclusion from the hearings of any person not necessary to the conduct of the proceedings. Plainly the laudable object is to spare the patient embarrassment. In that case, exclusion of a spectator should be on the patient's motion, to be consistent with legislative intent and avoid the constitutional question of the patient's right to a public trial.

Confinement in Jail Forbidden

Section 10 Subdivision 1 of the new law will forbid housing a patient who is detained under any provision of the Act in a jail. This will necessitate use of more distant facilities in those parts

Continued

*Section 7 Subdivision 2 is essentially similar in this respect to §§25.752 Subdivisions 1 and 3, but Section 1 Subdivision 6 of the new law will permit appointment of a certified consulting psychologist as one of the designated examiners in those areas of the state where no psychiatrist is available.

of the state not yet endowed with local psychiatric units. It may thus stimulate construction of needed psychiatric facilities locally where none now exist, where the degrading use of a jail cell to house a mental patient is now justified on grounds of expediency.

After Commitment

Release of patients following commitment is covered by Section 15 of the new Act.*

Review Board Created

The review board created by Section 16 Subdivision 1 consists of at least three people, one of whom "shall be qualified in the diagnosis of mental illness or mental deficiency" and one of whom "shall be learned in the law."

Right to Appear Before Board

Every six months the board shall visit each state hospital, at which time the board shall review the admission and retention of patients who request such review and report its findings to the commissioner. The avowed purpose of the section is to provide investigation of cases where there is doubt as to continuing need for confinement. The compensation provided in Subdivision 6, \$30 per day, is grossly inadequate for the services of a lawyer or psychiatrist and is bound to promote only the most cursory performance of the board's statutory duties.

Rights of Patients

Subdivision 1 of Section 17 will sharply restrict the use of restraints.

Subdivision 2 assures the patient's right to correspond without censorship with certain officials and with his physician and attorneys.

Subdivisions 3 and 4 will assure the patient's right to correspond without censorship with a registered individual other than the foregoing.

Subdivisions 5 and 6 will authorize restriction of the patient's communication with outsiders and receiving visitors where necessary for the medical welfare of the patient, although his personal physician and attorney shall be admitted at all reasonable times.

These subdivisions leave the clinician latitude in protecting the patient from his own indiscretions and from conduct which he might later regret. An example is the patient receiving electroshock. He may show transient coprolalia,* sexual aggression or simply incoherence. For this brief period it would be desirable to limit telephone calls and visits to named individuals who understand the situation rather than to allow the patient to humiliate himself unawares. No such rationale justifies cutting him off from physician or attorney. Nor in the example given is loss of civil rights for the entire period of the patient's hospitalization warranted.

Subdivision 8 will require consent of a patient for a serious surgical operation unless he has been previously adjudged legally incompetent.

Civil Rights Preserved

Perhaps the most sweeping reform is effected in Section 18, which provides that

(Subdivision 1): ". . . no person by reason of commitment, hospitalization, or treatment pursuant to this act shall be deprived of any legal right, including but not limited to the right to dispose of property, sue and be sued, execute instruments, make purchases, enter into contractual relationships, vote, and hold a driver's license. Commitment, hospitalization, or treatment of any patient pursuant to this act is not a judicial determination of legal incompetency . . ."

Subdivision 2 clearly establishes that determination of legal incompetency is a separate undertaking, which may be initiated before, during or after commitment proceedings.

A person acquitted as mentally ill under present law loses by statute or by administrative ruling all of the rights and powers preserved in the quoted new statutory provision, since his commitment operates as an adjudication of incompetency.

Mental Illness Does Not Imply Incompetence in Fact

The new Act recognizes that the degree to which mental illness impairs function varies widely and frequently has little to do with the rights which traditionally have been withdrawn from the mentally ill. It is far preferable to restrict pa-

*Substantially restates §525.753 Subdivisions 4, 6 and 7, §525.762 Subdivision 1, §253.18, §525.761 Subdivision 2 and §246.013.

**See Test Your Word Score Page 1359.

tients in particular activities on an individual basis rather than to blight an entire hospital population indiscriminately. For patients who are thought to be incompetent in fact separate statutory machinery will be available to protect them under the new Act.

Protection of the public will be achieved by curtailing the individual patient's activities as with passes or provisional discharge, which can be granted upon suitable conditions.

*New York Bar, the District of Columbia Bar and the Minnesota Bar.

Conclusion

Protecting the patient from his self-destructive conduct while at the same time preserving his constitutional rights to the maximum extent should be the goal of a truly progressive commitment statute. That goal demands psychiatric sophistication together with good legal draftmanship. With minor flaws the Minnesota Hospitalization and Commitment Act meets these demands admirably.

Southern Minnesota Medical Association Meeting

September 15, Faribault

The program for the meeting is listed below:

Carotid Endarterectomy in a Community Hospital—Case Report

J. G. Beaton, M.D.—Northfield
R. H. Meyer, M.D.—Faribault

Experimental Study on Complete Heart Block

D. W. Hannon, M.D.—St. Paul

The Ruptured Abdominal Aneurysm—A Diagnostic Problem

W. R. Schmidt, M.D.—Minneapolis

The Treatment of Acute and Chronic Sinusitis

C. F. Lake, M.D.—Rochester

Predictabilities of Back Injuries from the Orthopedic Surgeon's Standpoint

L. F. A. Peterson, M.D.—Rochester

Chemotherapy in Advanced Cancer

Moderator: Harry F. Bisel, M.D.—Rochester
Breast: John H. Brown, M.D.—St. Louis Park
G. I. Malignancy: Charles G. Moertel, M.D.—Rochester
Pulmonary Carcinoma: David T. Carr, M.D.—Rochester

Surgical Fate of Ureteral Stones: Lithotomy or Manipulation

William L. Furlow, M.D.—Rochester

Ileal Loop Substitute in Ureteral Injury—Case Report

Edward J. Richardson, M.D.—St. Paul

Closed Hemorrhoidectomy

Stanley M. Goldberg, M.D.—Minneapolis

Hepatic Injury and General Anesthesia

William H. Summerskill, M.D.—Rochester

Hysterical Repression of Pregnancy and Ensuing Infanticide

Dale W. Gullledge, M.D.—Rochester
Edward Litin, M.D.—Rochester

Surgical Treatment for Pulmonary Emphysema

W. Spencer Payne, M.D.—Rochester

Intravascular Coagulation in a Newborn—Case Report

Loren N. Vorlicky, M.D.—Edina

Subcutaneous Mastectomy

John Simons, M.D.—Rochester

Book Reviews

Some books, like the City of London, fare the better for being burned.—Tom Brown

INTERNATIONAL SYMPOSIUM ON THE NUCLEOLUS: ITS STRUCTURE AND FUNCTION—National Cancer Monograph 23 (December 1966). Edited by W. S. Vincent, and O. L. Miller, Jr. Published by U. S. Department of Health, Education, and Welfare, National Cancer Institute, Bethesda, Maryland. Text 574 pages, subject index 21 pages, and 57 plates. Price \$5.00.

The monograph is a collection of papers presented during the international symposium on the nucleolus at Montevideo, Uruguay, December 5-10, 1966. Thirty-five scientific talks were given; to mention a few: "Ultrastructural aspects of the normal and pathological nucleolus in mammalian cells," "Mode of formation of the nucleolus in plant cells," "Detection and origin of nucleolar components," "A model for ribonucleic acid function," "Nucleolar enzymes," and "Ribosome biogenesis."

Over-all theme of the symposium covered nucleolar desoxyribose nucleic acid, ribonucleic acid, proteins, and structure of the nucleolus. Desoxyribose nucleic acid appears to exist in the nucleolus in form of a tangled filament. The 18S ribonucleic acid is synthesized in the nucleolus rather than in the cytoplasm. About 80-90 per cent of the dry matter of the nucleolus is protein, a considerable fraction of which is ribosome-like.

Eight structural components of the nucleolus were presented: (1) Particulate components as seen under the electron microscope, (2) fibrillar components considered aggregates of protein, (3) amorphous components most likely to be proteins, (4) desoxyribose nucleic acid demonstrated by autoradiography, (5) nucleolonema predominantly composed of R N P as demonstrated by histochemical methods, (6) vacuoles which may contain proteins, ribosomes and other substances, (7) nucleolus-associated chromatin which is probably a random assortment of chromosomal material precipitated onto the nuclear surface, (8) perinucleolar structure, an as yet hypothetical membrane awaiting future studies.

It may be summarized that the nucleolus should not be considered a simple organelle with a single function, namely, the manufacturing of ribosomes, but rather a structure through which different materials flow, a processing area of several types of ribonucleic acids, proteins from one precursor to another till they leave the nucleolus through the nucleoplasm into the cytoplasm.

The Report of the Nucleolus Nomenclature Committee is given in the Appendix.

DIABETES FOR DIABETICS. George F. Schmitt: Diabetes Press of America; Miami, Florida, 1965.

"Diabetes for Diabetics" is a pocket-sized, slim, hard-cover treatise written for the diabetic patient. It contains detailed descriptions of diabetic therapy with many illustrations in color. Any literate adult could guide himself to the proper use of prescribed insulin by following the careful directions given by Schmitt. Probably an illiterate patient could do the same, by following the numerous pictures. There are also quite a number of color illustrations of food and kitchen items that are pretty to look at but of questionable value. In this category are pictures of a plastic teaspoon, a tablespoon, a can of soup, a tin of pork and beans. Any physician reading this book aimed at the lay public must temper his criticisms of a work not designed for his perusal. The public, however, deserves to be accurately informed. I question this "physiological" explanation of polyuria: "the kidneys have to remove the excess of unburned glucose; since the urine can only dissolve a certain amount of glucose, more urine must be passed." The statement "his life expectancy (the diabetic's) is approximately the same as others" is more optimistic than the facts permit. The statement "if he (the diabetic) disregards proper advice, he takes the risk of complications affecting the eyes, heart, kidneys, and nervous system" is true enough but implies that if he follows proper advice he does not assume these risks, an unwarranted implication. Several of these complications develop whether or not the patient is well controlled. However, these are minor irritations that probably will disturb only physicians and medical students who in any case will not use this work as a source of information. The diabetic patient can learn much about his disease from Schmitt's book and may achieve considerable reassurance, albeit reassurance not necessarily based on fact.

The college contribution

is a two-
way street

There are two ways to look at it.

There's the contribution the colleges make to business.

That's crucial.

Business employs about 42% of all college people. It uses their brainpower and skill in developing new products and methods. It fills management posts.

In the other direction, there's the contribution business makes to colleges.

The colleges welcome it. They need all the funds they can get. They're helping to prepare leaders for management, but the cost of education is going up.

In fact many colleges are having to turn away applicants—100,000 a year, says one estimate.

If business wants college talent, it must keep colleges in business. It can help finance their need for classrooms, facilities and especially teachers.

In this light, your aid-to-education program is an aid to your company.

Abstracts, Briefs and Commentaries

Aspirin and Von Willebrand's Disease*

Few know more about diagnosing bleeding diseases than Armand J. Quick. He conceived the prothrombin time in the thirties, pioneered its clinical use, has written scores of papers on coagulation, and ranks as an international authority on blood clotting.

Recently, then, when Doctor Quick wrote on how to diagnose Von Willebrand's disease with aspirin, I read closely what he had to say.^{1,2} For if one excludes the hemophilias, this is probably the commonest congenital bleeding disease. Yet many physicians have never recognized a case. Why? One reason may be that they neglect the bleeding time. In *most* patients with the disease, this crucial test is prolonged. I emphasize "most" because some patients with known disease have normal bleeding times.

In these patients, Doctor Quick uses aspirin for diagnosis. He takes a patient who bleeds abnormally, does an ear bleeding time, gives the patient two five-grain aspirins, waits two hours, and repeats the bleeding time. This he calls an aspirin tolerance test. If the first bleeding time lasts for three minutes or less, the second extends five minutes or more, and the patient has a family history of bleeding, Doctor Quick diagnoses Von Willebrand's disease.

At least that is how I interpret his facts. He took students, measured their bleeding times before and after aspirin, and found a slight prolongation of bleeding time in more than half. Then he did the same with six patients—a young man and his two sisters, and a mother and her two daughters—in whom he suspected Von Willebrand's disease. Before aspirin, bleeding times of four of these patients were 3, 3.5, 3, and 3 minutes, all borderline values; after aspirin, their times were 6.5, 10, 5.5, and 7 minutes.

From this little experiment he concluded the aspirin tolerance test "makes it possible to detect mild cases in which basic bleeding time is normal . . . the basic abnormality appears to be the lack of a factor that is further depressed by aspirin."

THE BLOODY NOSE*

It should be reassuring for parents to know that nosebleeds during childhood, puberty, and adolescence are rarely serious. Mothers can often control the bleeding by pressing the child's nostrils together for about 10 minutes and applying cold compresses.

Nosebleeds in elderly persons can be severe because of high blood pressure and hardening of the blood vessels. Treatment for these is best done in a hospital and consists mainly of packing the nostrils and ligating blood vessels.

Even if the bleeding is severe and prolonged, it should be comforting for the public to know that it rarely causes death.

Nosebleeds seldom result from deficiencies in the clotting mechanism of the blood.

O. Erik Hallberg, M.D.
Rochester, Minnesota

*Given before a meeting of the Minnesota State Medical Association, Duluth, May 15 to 17, 1967.

THE DISCHARGING NIPPLE*

Abnormal secretions from the breast may be defined as any nipple discharge unrelated to pregnancy. Such abnormal breast secretions, whether they are bloody or clear, may indicate the presence of a breast cancer and, therefore, can never be dismissed lightly.

The causes of abnormal breast secretions include benign tumors, inflammation, hormonal factors, certain drugs including various tranquilizers, local stimulation, injury, and various forms of breast cancer. Fortunately, most abnormal breast secretions are due to benign factors, but the burden of proof is always on the physician.

The methods for making an accurate diagnosis of abnormal nipple discharges were presented. When surgical removal of a portion of the breast is necessary for diagnosis, an adequate operation can be done with good cosmetic results. Doctor Anderson condemned the surgical removal of the entire breast without a specific diagnosis of cancer, except in the male. The higher incidence of breast cancer in the male with a true nipple discharge and the cosmetic insignificance of removal of the male breast justified mastectomy in the male for diagnostic purposes in many instances.

David P. Anderson, Jr., M.D.
Austin, Minnesota

*Summary of presentation made during annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, May 15, 1967.

THE INTENSIVE CARE UNIT—CAN THE COMMUNITY HOSPITAL AFFORD IT?*

Coronary heart disease is the greatest single cause of death in the United States. Over a million people die annually, half of these despite standard hospital treatment. Eighty per cent of all deaths are due to arrhythmias, cardiogenic shock or congestive heart failure. These lethal complications arise suddenly but seldom without warning signs. Early treatment of arrhythmias and arrhythmic-induced shock and congestive heart failure is dependent on prompt diagnosis. The use of continuous EKG monitoring can prevent many of these fatal complications.

*Summary of panel presentation, Minnesota State Medical Association Meeting, Duluth, Minnesota, May 15, 1967.

It remains for each hospital staff to evaluate the magnitude of the problem in its community. Larger hospitals (300 beds or more) will probably find it feasible to establish a fixed area, coronary care unit. If interne and resident coverage is not available, highly specialized coronary care nurses must be trained and regularly drilled in fundamentals of cardiopulmonary physiology, EKG pattern recognition, emergency treatment, cardioversion, and general nursing techniques.

Smaller hospitals will find the portable monitoring systems with rate alarms more economical and practical.

All hospitals must have emergency cardiac resuscitation equipment, and the staffs must assume the responsibility of training resuscitation teams.

Physicians responsible for the establishment of such units and teams in the community hospital must realize that a program requires some hardware (electronic monitoring equipment with a defibrillator) and much software (cardiac nurse specialists, training programs) if success is to be achieved.

W. J. Henke, M.D.
St. Paul, Minnesota

PAINFUL FEET*

A practical short presentation for surgical correction of painful foot conditions is presented to the Doctors' Assembly by a practicing orthopedic surgeon. Six of the seven conditions of the feet, surgically correctable, have visible abnormalities that can be seen by anyone. Many of these enlargements, calluses, or nail deformities are aggravated by footwear.

The purpose of this discussion is to show interested surgeons what they might do to help ailing feet and to show all physicians what surgery of the foot can accomplish for their patients. Interested surgeons can learn the techniques without difficulty and help the majority of patients with these common conditions. More involved procedures may be reserved for the orthopedic surgeon.

Bunions are ordinarily most troublesome in women because of the tight fit of the shoe to keep it on the foot. Removal of the mass on the inside of the great toe and removal of a portion of the bone of the toe will create a false joint. This new joint will permit the toe to straighten and relieve pain from motion and from pressure of footwear.

Infected or uninfected *ingrown toenails* may be improved or eradicated by simple removal of tissue on the lateral borders of the involved toe. Such toe removal would include all parts of the nail down to the root. This conservative and effective measure is presented to counter the more painful and long-healing measure of removal of the whole nail itself.

Bent toes, *hammer toes*, claw toes may be corrected by division of tendons or by removal of the most prominent bone under the callus. A callus may develop around the fifth toe opposite the bunion position. This is called a *bunionette*. Here again, removal of underlying bone is effective for relief.

The one painful condition, not visible to the patient or the surgeon, is the pinched nerve or *Morton's toe*. This nerve irritation causes burning, cramping, and alters sensation at the foot near the third and fourth toes. It is worse on activity and weight-bearing. It is relieved by rest and removal of footwear. On removing the shoe, the patient massages the foot for relief. Again, application of the shoe with walking re-creates the problem. Removal of the nerve deep in the web between

*Presentation made during annual meeting of Minnesota State Medical Association, Duluth, Minnesota, May 15, 1967.

Continued

the third and fourth toe relieves the problem.

Procedures may be carried out under local or general anesthesia. The volume of local anesthesia is to be kept to a minimum. Medications which constrict the blood vessels are not used in the foot.

The surgeon performing these simple measures will add to the comfort and happiness of many of his patients. Each locality should have at least one doctor interested in surgery of the forefoot.

Kenath H. Sponsel, M.D.
Minneapolis, Minnesota

THE BUZZING EAR*

Tinnitus is the term applied to the noises heard in one or both ears by a patient when no extraneous sounds are audible. In most cases the cause is due to degenerative processes in the cochlea of the inner ear. When this is the case, no treatment is of much value, even though the noise can become severely irritating to the patient.

At times, however, the noise is a symptom of a condition which should be investigated. Conditions such as certain drug overdoses, brain tumors and dangerous narrowings in the blood vessels to the head will cause characteristic noises in the ear. Other correctable conditions of the ear will often produce tinnitus as an early symptom.

For these reasons, the individual suffering from an annoying ear noise should be fully examined to determine the cause. For those fortunate people in which a correctable condition is found, early treatment in some can often reverse a potentially lethal process; while in others, hearing loss can be prevented. For those with inner ear conditions which cannot be treated effectively, the physician can offer supportive therapy to help make the patient less aware of the noises during the quiet periods of the evening and night when these noises are most irritating. For those with severe tinnitus, use of a clock radio at bedtime is very helpful in allowing the patient to fall asleep with music blocking out the head noises.

Barclay M. Cram, M.D.
St. Paul, Minnesota

*Presentation made during Minnesota State Medical Association Meeting, Duluth, Minnesota, May 15, 1967.

AMNIOTIC FLUID EXAMINATION AND EARLY DELIVERY FOR ERYTHROBLASTOSIS.*

With modern methods of management most babies suffering from erythroblastosis fetalis may now be saved. In former years erythroblastosis fetalis, a condition caused by antibodies forming in an Rh-negative mother's blood against the red cells of her unborn Rh-positive baby, was fatal in 50 per cent of cases. Although treatment with replacement of the affected baby's blood with Rh-negative blood has been highly effective for 20 years, it has been of no avail for the 25 per cent of erythroblastotic babies who die of their disease before delivery.

Early delivery has been practiced with success in Winnipeg for the past 13 years but is dependent upon the accurate prediction of severity of erythroblastosis before the baby is born. Until recently, history of previously affected babies and the strength of the antibody in the mother's blood were the only means of determining

*Summary of presentation in the panel on Erythroblastosis, Minnesota State Medical Association Meeting, Duluth, Minnesota, May 16, 1967.

how sick the baby was. These two indicators were only 62 per cent accurate in predicting severity of disease.

Optical Density

With the addition of amniotic fluid examination accurate prediction of severity of erythroblastosis in the unborn baby has risen to 95 per cent. Amniotic fluid, the fluid in which the baby floats, is swallowed and voided by him. The test used to determine severity of disease in the fetus involves removal of a small amount (two teaspoons) of amniotic fluid through a needle inserted under local anesthetic through the pregnant mother's abdomen into the uterine cavity. The fluid is protected from light which destroys its usefulness and is examined in a spectrophotometer. Optical density readings are made at various wave lengths and a measurement of the increase in optical density at the wave length 450 m μ is made. It is this increase in optical density which mirrors the severity of erythroblastosis. These measurements have been a great help in determining which women have babies so severely affected with erythroblastosis that they must be delivered early for any hope of survival and which women have babies which may safely be left to deliver at term. On the basis of an aggressive policy of early delivery in selected cases of erythroblastosis in the past four years 59 women in Winnipeg have had their babies delivered six or more weeks before their expected dates. Forty-eight of the 59 have had surviving babies. Seven of the 48 have come from the United States.

Amniotic fluid examination has also proven of great value in selecting the one sensitized Rh-negative woman in 12 whose unborn baby will die so soon that early delivery is valueless and in whom pre-birth intra-uterine transfusion must be undertaken.

John M. Bowman, M.D.*
Winnipeg, Canada

*Clinical Director, Rh Laboratory, Associate Professor Paediatrics, University of Manitoba.

THE INTENSIVE CARE UNIT—CAN THE COMMUNITY HOSPITAL AFFORD IT?*

With the advent of Intensive Care Units in hospitals there must be a re-evaluation of the possible and potential legal exposure that hospitals and doctors may face by way of claims by patients that have been placed on intensive care in these units.

It should first be recognized that the modern trend of courts and juries has been to put a greater responsibility in general on hospitals as to the care that they expect to receive in all phases of hospital treatment.

The addition of the Intensive Care Unit to hospital services can present unique problems from a medicolegal standpoint. The very title, incorporating the words "Intensive Care," seems to beg for a claim by the public and particularly by a patient demanding: "Did I receive intensive care?" We must therefore explore this potential legal problem of additional claims and decide what efforts can be made to avoid them.

It is suggested that physicians can do much to alleviate the problem by using their office as hospital staff members to be sure that the nursing staff and hospital per-

*Presentation given during annual meeting of Minnesota State Medical Association in Duluth, Minnesota, May 15, 1967.

Continued

sonnel are adequate in number and properly trained. Some hospital staffs have seen fit to place the Intensive Care Unit under the Department of Anesthesiology, thereby centralizing the responsibility for the operation of the unit.

As attending physicians, the members of the medical profession can also do much to protect themselves and the hospital by proper education of their patients and patients' families about the function of the Intensive Care Unit and the necessity therefor. It seems imperative that when a physician puts a patient in an Intensive Care Unit, he himself assume added responsibility to be more detailed in the orders given and satisfy himself at frequent intervals that those orders are being complied with. It is further suggested that the attending physician familiarize himself with the nursing personnel on duty and work closely with that personnel on a teamwork basis.

There is a concerted effort at the present time to bring the Intensive Care Unit to the small community hospital, especially in the area of cardiac care units. Since the problems confronting the small community hospital will be essentially the same as those confronting the large metropolitan hospital, many of the problems may be more difficult to resolve because of lack of sufficient trained personnel. The establishment of the Intensive Care Unit in a small community hospital will obviously place a greater burden on the smaller staff of physicians available for supervision of the unit, thus requiring greater cooperation from the local physicians to guarantee successful operation of the unit.

With the rapid development in medical technology it is difficult to see how a large hospital can afford to be without an Intensive Care Unit, and it is certainly desirable for the small community hospital to have such a life-saving unit available. However, we must at all times recognize the potential legal pitfalls confronting the hospital and its staff if the unit is not properly managed and operated.

Jerre F. Logan*

Seasonal Diseases

The diseases of *spring* are, maniacal, melancholic, and epileptic disorders, bloody flux, quinsy, coryza, hoarseness, cough, leprosy, lichen albus, exanthemata mostly ending in ulcerations, tubercles, and arthritic diseases.

Of *summer*, certain of these, and continued, ardent, and tertian fevers, most especially vomiting, diarrhea, ophthalmia, pains of the ears, ulcerations of the mouth, mortifications of the privy parts, and the sudamina.

Of *autumn*, most of the summer, quartan, and irregular fevers, enlarged spleen, dropsy, phthisis, strangury, lenteria, dysentery, sciatica, quinsy, asthma, ileus, epilepsy, maniacal and melancholic disorders.

Of *winter*, pleurisy, pneumonia, coryza, hoarseness, cough, pains of the chest, pains of the ribs and loins, headache, vertigo, and apoplexy.

—Hippocrates

The only thing everybody understands about money matters is that it does.

—Changing Times

A large, dark, grainy microscopic image showing numerous spermatozoa. The sperm heads are visible as bright, oval shapes, and their long, thin tails (flagella) are seen as wispy, hair-like structures extending from the heads. The background is dark and textured.

New view of an oral contraceptive at work

Although suppression of ovulation remains the primary mode of action of oral contraceptives, newer knowledge indicates that products like Norinyl-1 — a combination of both low-dosage progestogen and estrogen for the full treatment cycle — may provide multiple action that helps explain their unexcelled record of contraceptive effectiveness. This report explores the possible secondary protective mechanisms offered by combined hormonal administration.

Accumulating evidence has indicated that sparse, highly viscous cervical mucus has a possible adverse effect on the motility and survival of spermatozoa.

The estrogen-opposing progestational ingredient of Norinyl-1 (norethindrone 1 mg. with mestranol 0.05 mg.) changes the usual mid-cycle picture of a thin, watery cervical mucus. The result — a built-in barrier that appears to inhibit sperm from reaching the ovum should one be released. The inset in the adjoining photograph shows immobile spermatozoa as they appear in cervical mucus taken from a patient treated with Norinyl-1.

How the estrogen-opposing action of Norinyl-1 creates cervical mucus that may be hostile to sperm penetration

Normally, estrogen activity during the fertile midcycle stimulates the production of a profuse and watery cervical mucus that permits maximum sperm motility and promotes penetration.

But what happens when Norinyl-1 is administered? Its potent progestogen, norethindrone, opposes estrogen stimulation of cervical mucus. Consequently, the amount of mucus decreases and its viscosity increases. This results in a sparse but thick mucus barrier that appears to diminish the vitality of the sperm and to impair its powers of penetration.

The role of viscous cervical mucus as a secondary action of Norinyl-1

In a report on 89 patients taking this medication,* cervical mucus obtained from cycle day 5 to cycle day 29 appeared scant and thick and exhibited little or no Spinnbarkeit.

In the opinion of this investigator, the effect on cervical mucus may be sufficient to prevent conception.

*Cohen, M. R.: Symposium: Mechanisms of Action of Low Dosage Oral Contraceptive, Yale University Medical Center, New Haven, Conn., April 6, 1967.

Normal cervical mucus at midcycle in untreated patient is known to permit sperm motility... promote sperm penetration.

Cervical mucus is thin and watery with a stretchability (Spinnbarkeit) of 15 to 20 cm.

Thin, watery mucus crystallizes into this well-defined, fernlike pattern within a minute.

Spermatozoa appear healthy, are active and freemoving.

Viscous cervical mucus at midcycle produced by Norinyl-1 appears to impair sperm vitality... inhibit penetration.

Cervical mucus is scanty, thick and viscous. Spinnbarkeit is 1 cm. or less.

In thick, viscous cervical mucus the fern pattern is poorly defined or absent.

Immobile spermatozoa as they appear in cervical mucus taken from a patient treated with Norinyl-1.

How Norinyl-1 alters normal endometrial responses— another possible protective mechanism

Let us suppose that an ovum is released—as occurs in an occasional, rare case—and somehow a sperm succeeds in penetrating the cervical mucus barrier. Should this come about, one additional action of Norinyl-1 may protect the patient from unwanted pregnancy. The theory is that progestogen intake makes endometrial tissue unreceptive to implantation.

Endometrium of
untreated patient

Normally, the endometrium progresses through a proliferative phase stimulated by estrogen and a secretory phase stimulated by progesterone. During the secretory phase the endometrium is receptive to the fertilized ovum.

Endometrium produced
by Norinyl-1

When Norinyl-1 is administered its progestogen component—norethindrone—accelerates the secretory phase and suppresses glandular and vascular development.

effective fertility control
on half the previous dosage
maintains ratio
of the established
norethindrone/mestranol
combination
lower cost

new Norinyl-1[®] tablets

(norethindrone 1mg. $\bar{c}$ mestranol 0.05mg.)

Reduction of oral contraceptive dosage to lowest effective levels has become a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now available in a new strength in which both norethindrone and mestranol are reduced 50 percent. Studies show that Norinyl-1 achieves fertility control with only 1.05 mg. of combined progestogen and estrogen per tablet.

Norethindrone was first reported for use as a progestational agent in human beings in 1955. Norethindrone 2 mg. with mestranol 0.1 mg., as an oral contraceptive, is currently in use by over 2,000,000 women. Clinical experience now establishes that Norinyl-1 also amply meets the criteria of reliability and safety.*

*Symposium on Low-Dosage Oral Contraception, Palo Alto, Calif., July 15, 1965.

PRESCRIBING INFORMATION

Contraindications: 1. Patients with thrombophlebitis or with a history of thrombophlebitis or pulmonary embolism. 2. Liver dysfunction or disease. 3. Patients with known or suspected carcinoma of the breast or genital organs. 4. Undiagnosed vaginal bleeding.

Warnings: 1. Discontinue medication pending examination if there is sudden partial or complete loss of vision or if there is a sudden onset of proptosis, diplopia, or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. 2. Since the safety of Norinyl-1 in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. 3. Detectable amounts of the active ingredients in oral contraceptives have been identified in the milk of mothers receiving these drugs. The significance of this dose to the infant has not been determined.

Precautions: 1. The pretreatment physical examination should include special reference to breast and pelvic organs, as well as a Papanicolaou smear. 2. Endocrine and possibly liver function tests may be affected by treatment with Norinyl-1. Therefore, if such tests are abnormal in a patient taking Norinyl-1, it is recommended that they be repeated after the drug has been withdrawn for 2 months. 3. Under the influence of estrogen-progestogen preparations, preexisting uterine fibroids may increase in size. 4. Because these agents may cause some degree of fluid retention, conditions that may be influenced by this factor, such as epilepsy, migraine, asthma, cardiac, or renal dysfunction, require careful observation. 5. Although a cause and effect relationship has not been established, Norinyl-1 should be used with caution in patients with a history of cerebrovascular accident. 6. In relation to breakthrough bleeding, as in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are

indicated. 7. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. 8. Any possible influence of prolonged Norinyl-1 therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. 9. A decrease in glucose tolerance has been observed in a small percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Norinyl-1 therapy. 10. Because of the occasional occurrence of thrombophlebitis and pulmonary embolism in patients taking oral contraceptives, the physician should be alert to the earliest manifestations of the disease. A cause and effect relationship has not been demonstrated. 11. Because of the effects of estrogens on epiphyseal closure, Norinyl-1 should be used judiciously in young patients in whom bone growth is not complete. 12. The age of the patient constitutes no absolute limiting factor, although treatment with Norinyl-1 may mask the onset of the climacteric. 13. The pathologist should be advised of Norinyl-1 therapy when relevant specimens are submitted.

Side Effects: The following adverse reactions have been observed with varying incidence in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms, breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma, breast changes (tenderness, enlargement and secretion), loss of scalp hair, change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately postpartum, cholestatic jaundice, erythema multiforme, erythema nodosum, hemorrhagic eruption, migraine, rash (allergic), itching, rise in blood pressure in susceptible individuals, mental depression.

The following occurrences have been observed in users of oral contraceptives. A cause and effect relationship has not been established: thrombophlebitis, pulmonary embolism, neuroocular lesions.

The following laboratory results may be

altered by the use of oral contraceptives: increased bromsulphalein retention and other hepatic function tests, coagulation tests (increase in prothrombin, factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T₃ values), metapyrone test, pregnanediol determination.

Other side effects reported to have occurred in association with use of this drug are dizziness, hirsutism, pains in legs, back, chest and abdomen, dysuria, drowsiness, vaginal discharge, libido increased and decreased, eruptions, hypermenorrhea, hypomenorrhea, increased appetite, G.U. infections, varicose veins, abdominal fullness, acne, headache, nervousness, allergies, blurred vision, pain in eyes, and itching in eyes. For complete clinical data, see package insert.

Dosage and Administration: 1. One tablet of Norinyl-1 is administered orally for 20 days beginning on day 5 of the menstrual cycle. (Count day 1 of the cycle as the first day of menstrual bleeding.) Repeat this dosage schedule for each cycle. 2. If no menstrual period occurs after a cycle of treatment (20 tablets) in which patient adhered to the schedule, the patient must be instructed to resume taking the Norinyl-1 tablets 7 days after the previous 20-day course was completed. For example, if the last pill of a previous cycle had been taken on a Sunday, then a new cycle of treatment should begin on the following Sunday. 3. In the postpartum woman, it is recommended that the first cycle of treatment should begin on day 5 of the first menstrual cycle. However, Norinyl-1 should not be administered during lactation.

Availability: Norinyl-1 (norethindrone 1 mg. with mestranol 0.05 mg.)—Dispensers of 20 and 60 and bottles of 250 tablets.

What of Tomorrow?*

OWEN H. WANGENSTEEN, M.D.**
Minneapolis, Minnesota

Your Outlook and Opportunity

TRADITIONALLY the significant occasions in our lives are birth marriage, and death. To these I would add graduation, signaling entrance upon life's tasks.

This is a moment to which you and your families have looked forward for a long time. There have been years of planning and saving. Days of frustration and disappointment too, with interspersion of inspiration and crystallization of hopes. You present testimony as well as evidence that a medical school is a place where medicine is studied as well as taught. While you are now definitely on your way, only a beginning has been made.

A century ago, Sir James Paget,¹ a well known British Surgeon-Teacher, remarked to a graduating medical class—"What will become of you?" The pattern of Paget's day probably remains the same today. I know the work of a number in this class well enough to believe that many of you are destined for careers of unusual distinction, whether in practice in a small or large community or in the advancement of a discipline. Many of you will become Teachers and regale your own professional children with progressive extensions of the lessons you have put to a good account. Some of you may become Casanovas of the inkwell unless an early case of authors' lead poisoning persuades you to desist.

The promise of success can be foretold most accurately by the spirit of your dedication and motivation. In this life one can have almost anything he wants, granted he wants it enough to

work for it in and out of season. The difficulty is that our wants are so many and it is so easy to equate want with need. Between these, as Leon Tolstoy indicated, and as many learn only too late, there is a significant difference. Our needs actually are few. Our wants are limitless. He who wishes to succeed at everything may become a very versatile person but is unlikely to acquire distinction in many or any of those interests. The best known aphorism of Hippocrates is that art is long and the acquisition of learning difficult. In order to succeed, one must be ready to accept Hippocrates' wisdom as a guideline. Obviously, Hippocrates did not write those sage words as a young man.

The outlets for the young physician are numerous. Fortunate is he who decides early in his career what he would like to do and then marches slowly, relentlessly, and without interruption toward its achievement. It is not the goal itself, but the struggle toward its achievement that constitutes the true reward.

The real paymaster of any of us is opportunity—to serve, create, improve and relieve. Those of you who enter active practice and are willing to walk this trail with no desire other than to bring healing and relief from suffering to your patients will encounter a depth of gratitude not surpassed by any other type of remuneration.

If I had Fortunatus' wishing cap and could grant you three wishes, I would wish you great enthusiasm for your work, a spirit of industry and consecutiveness, accompanied by an appreciation of and love for your fellowman. With these compelling incentives, you could not fail no matter where life's adventure takes you.

Continuing Fission of Biologic Disciplines

During my earlier years in surgery, by spend-

Continued

*Presented at the University of Minnesota Recognition Program honoring the Senior Class in Medicine, Friday, June 9, 1967.

**Department of Surgery, University of Minnesota Hospitals, Minneapolis, Minnesota.

ing every Saturday afternoon in the library, I could gain a nodding acquaintance with all the current surgical literature of the world. Today, if a young surgeon read every waking minute he could not begin to do this. After acquiring a broad background of training in the discipline of one's election, it is necessary to concentrate on a smaller field to acquire some suggestion of expertise. A challenging summons comes also from the Public to get on with medical research in quest of better solutions of present-day problems.

Instruments of Precision

A century ago, instruments of precision brought new medical disciplines into being; witness the cystoscope, ophthalmoscope, otoscope, laryngoscope. Roentgen's great discovery (1895) made a terrific impact upon 20th Century medicine, as did the birth of microbiology and knowledge of infection a few decades earlier. The present continuing fission of biological disciplines reflects essentially a conflux of archipelagos of ideas converging into peninsulas of information, thus creating by mitosis and fusion new biologic systems from which the Profession and the Public may rightfully look to virgin techniques accelerating significant new developments.

I have the boldness to believe that the biologist-historian, by studying extending peninsulas of knowledge in the interphases between biologic disciplines, with the help of librarians and interested biologists in the disciplines involved, can speed discovery and lend meaning to knowledge. One need only think back upon the significant preludes to Lister. Many had written that antiseptic management of wounds saved life and diminished or precluded suppuration of wounds, but little note was taken of their publications until patrols and later armies of microbes were marshalled onto the scene to support their position.

Extra-Corporeal Oxygenation

The most exciting development in Surgery during my tenure has been that of intracardiac surgery, much of the history of which was written here. All of you have been witnesses to this development. What you must appreciate, however, was the importance of the background of training for the men who gave impetus to this development. Techniques of oxygenating the heart without lungs were long known to students of the circulation. When, however, surgeons

trained in physiologic techniques and with dedication matched by imagination and courage, undertook exploration of the problem, this combination made the venture a great success. For a period of more than 30 years, with the helpful cooperation of colleagues in other disciplines, and particularly with M. B. Visscher, Professor of Physiology, it has been the objective of the Surgery Department to see to it that every surgeon with academic aspirations has a training in a basic medical discipline.

Students of tissue transplantation will need orientation in many fields, notably genetics, radiology, and pharmacology to overcome the disturbing factors of antigenicity and incompatibility which now stand in the way of its progress.

Metchnikoff, Methuselah and Prospects for Prolongation of Useful Life

"From 20 to 50 man should live for himself and his family; from 50 to 100 for science and humanity, and after a hundred for the State. . . . We should live till 140 years of age."

Three Score and Ten

Some of you may infer that these words were born in the mind of a current visionary. I hasten to add that Elie Metchnikoff² authored that dreamy prediction in 1903 when he was 58; he died at 71. The Biblical seers understood better the promises of old age than did Metchnikoff or modern prophets who are fond of predicting useful lives to 100. The 90th Psalm reminds us that "the years of man are three score and ten and if by strength they be four score years, yet is their strength but labor and sorrow." It has been my privilege and obligation over long years to have had much to do with persons in the 9th decade of life. Without exception, they want to continue their existence as long as they find the company of their associates reasonably acceptable. Occasionally one meets a person who is strong in body and mind in his late 80's, but such are few indeed. Methuselah's only distinction, apart from being Noah's grandfather, was his age. Methuselahs are currently not popular in any market and make no appeal in the marriage mart either, unless accompanied by a substantial bank account.

The Library, Books and Reading

High on the agenda of the needs of this Medi-

cal School during my tenure was a biomedical library. The pressure of other necessities pushed it aside for many years. Your class has been amongst the first to have the advantage of ready access to a fine collection of books. In books one finds his life influenced by great teachers of the past. Many of you have probably observed on a wall of our Surgical Conference Room the nice incentive to reading by Anthony Trollope³ (1862): "With reference to the habit of reading, I make bold to tell you it is your pass to the greatest, the purest and the most perfect pleasures that God has prepared for his creatures. . . . When a young man looks into a girl's eye for love, and finds it there, nothing may afford him greater joy for the moment: When a father sees a son return after a long absence, it may be a great pleasure for the moment: But the habit of reading is the only enjoyment I know, in which there is no alloy. It lasts when all other pleasures fade."

Pressures of the Expanding Curriculum

It is unfortunate that in our schools the pressure of examinations often forces the student to concentrate on examinations rather than to increase his stores of knowledge. It has long been my view that if all the disciplines from anatomy to zoology were taught from an historic point of view, emphasizing those items which survived the erosion of time, our medical students would be better informed. It will interest you to know that the text books in surgery recommended to the first graduating class in medicine from this School 75 years ago were as large as those of today. Yet, surgery of the great vessels and the thorax, including the lung, heart and esophagus, as well as the cranium, was unknown. The truth of the matter is that much of what is taken for gospel truth in many current-day textbooks just is not so, as future enlargements of knowledge show.

Preparation for Practice

Samuel Johnson⁴ said, in advising a native Virginian contemplating the study of medicine abroad: "The Scotch like a house built to last a man's lifetime only. The English like a palace or fortress intended to last many ages. The first build lightly, the last lay a very strong and firm foundation

before they begin the work." We might do well to ponder the critique of Sam Johnson, who appreciated that education at Oxford or Cambridge preliminary to pursuit of conventional medical training at London in his day took approximately 14 years. If we perpetuate our present long scheme of training, we shall never recruit enough personnel to fill the ranks. More than 30 years ago Will Mayo,⁵ long a Regent of this University, believed that medical schools should begin to think of varying lengths of training for physicians.

Changing Character of Medical Practice

Today there are more physicians in the United States than there were in the entire world in 1880;^{*5a} yet there are not enough. Our Boards of Licensure have had to relax rules for admission to practice for foreigners in the interest of the needs of our people. How is this great existing demand to be met? The cry of the public is for more physicians pursuing Family Practice. Every hamlet wants its doctor.

Reduce Training Period

The only way we can have more physicians is to make the field of medicine more attractive. The training period must be reduced. Presidents, Congressmen, and business executives learn on the job and so too do University Professors. By eliminating one year in elementary school, another in high school, another in college, and by omitting the internship, the training of prospective physicians could be reduced by approximately four years. Physicians would be graduating at the age of 22 to 23 instead of 25 to 27. They could employ the salvaged time usefully in preparation for their life's work.

Family Practitioners

Are there other sources for Family Practitioners? When our Medical School began, there were two charters, one for the practice of medicine, one for homeopathy. By the year 1909, homeopathy had been dropped from the curriculum and became fully absorbed by the profession. There are probably now approximately 15,000 osteopaths in the United States. Our profession accepts them. In fact, one of the colleges of osteopathy has been converted into a full-fledged medical school. My occasional contacts with those who profess oste-

Continued

*5a. John Shaw Billings (1881) indicated there were 180,000 physicians in the world then and 65,000 in the U. S. An item in the New York Times suggests there are now more than 300,000 physicians in the U. S.

opathy would be to encourage most, if not all of their graduates to become Family Practitioners. Of the 109 osteopaths in Minnesota, only two have full hospital privileges; an additional 20 may prescribe drugs and perform minor surgery.⁶ An extension of their prerogatives could help resolve our poor showing in providing ready access in peripheral areas of our State to competent medical care. More and more patients of Family Physicians come to their offices; house calls are becoming far less frequent. So it is too in England. A recent report⁸ indicates that 85 per cent of the Family Physicians' practice in the midlands of England is performed in the doctor's office. Moreover, their Family Physicians perform only minor surgery, a trend that is growing here too. The Family Physician, in clinics and medical centers, will come to occupy a unique role between specialists and his community of patients. Osler Peterson,⁹ an ardent student of the problem of medical care and a graduate of our School, advocates reorganization and redistribution of medical care, emphasizing the need for more effective regionalization of hospital service. In such a scheme, the Family Physician too will carve out a useful niche in the Hospital Team. Medical Center Hospital practice will in time come to supersede solo office practice. Recruitment of a million paramedical people for our hospitals and medical centers would permit physicians to extend their services usefully to larger numbers of patients.

The Clinic Idea

Certainly the trend is towards specialization. The "clinic idea", to which the Brothers Mayo lent such great impetus, might well become standard practice everywhere. Directly following World War II, through the activation of the Hill-Burton Act, the Government built well equipped hospitals throughout our country. There are now 67 hospitals in Minnesota, fairly well dispersed throughout the state, that are beneficiaries of such support. In some states, notably Oklahoma,⁷ a cooperative enterprise among these community hospitals and the State University has come into being, with a studied attempt to bring in well qualified specialists cooperating fully as Teams with the physicians in the area, with other existing clinics and with the University Medical Center. An extension of this principle could bring a superior brand of medical practice into almost every area of our State.

At the Minnesota State Medical Association meeting held in Duluth in May, in chatting with practitioners whom I have known well over the years of my tenure here, I was told of increasing numbers of villages and towns in Minnesota without physicians.

Emolument

What of emolument? I am of the opinion that satisfying conditions of work constitute the best paymaster of the physician. Whereas mink coats and Cadillacs continue to be symbols of success for the business executive, the physician, with satisfying conditions of work, and the medical scientist too, whether clinician or experimentalist, does not need these ostentatious symbols of success. Their reward lies primarily in enviable opportunities, in the gratitude of patients and in the knowledge of spending their lives in the betterment of man's lot. J. Pierpont Morgan quoted St. Paul correctly when he said, it is not money but "the love of money that is the root of all evil."

Time is the most important commodity we have and whether primarily engaged in the practice of medicine, the care of patients, or in medicine's advancement, to have the opportunity of pursuing one's primary objective is indeed compensation which exceeds all others in value.

The Future

What of the future? Throughout the ages, great figures in medicine like Ambroise Paré have predicted that medicine has already reached maximal achievement. Said Paré in 1575: "Posterity will not be able to surpass us (be it said without malice or offense) save by some additions such as are easily made to things already discovered."¹⁰

Twenty-five years ago who could have foreseen the development of intracardiac surgery within a decade? Who can predict what physicians will be doing in the year 2000? Certainly many disciplines yet unknown will come into being, making this an exciting time in which to live and work.

The world has always been in a confused state. Did not Job admit that his affliction was in part confusion? If all the costs connected with the preparation for war could be expended upon man's improvement, rather than upon bringing those who oppose us to their knees, what a Utopia

this could be!

On the smaller stage of our own work, each of us by example and commitment to those objectives for which our profession stands can make our contribution to the improvement of man's lot. Was this not the Great Master's appraisal of how best to spend one's life? In your work, by enriching the lives of those whom you are privileged to serve, you repay your debt to Society for the splendid opportunity of a medical education.

Gratitude is a wonderful quality. You will recall that the physician St. Luke reminds us that the Great Master healed ten patients with leprosy but only one returned to give thanks. Scriptures tell us too that the Lord loves a cheerful giver. When you find yourselves more affluent than now, remember that the Medical School and its Minnesota Medical Foundation appreciate and understand the warm spirit of gratitude manifested by that Samaritan leper who recognized his obligation.

However much we appreciate and take pride in the accomplishments of our School, it is even more important that we cultivate a spirit of warm affection and gratitude toward it. Our School, however, is not neutral in gender but distinctly feminine—Alma Mater, our spirited foster Mother. Keep her always high in your thoughts and

affections.

In conclusion, let me remind you once more that what you wish for in youth and work for persistently with diligent perseverance, in time you will have in abundance.

A boy who grew up in the shadow of our State Capitol and who became a famous investigator and Teacher relates how his dying mother called him to her bedside to leave an instruction for his future. Said the mother¹¹ to her 10-year-old son: "Walter, be good to the World," and that Walter Cannon did, every student of Medicine and Physiology can appreciate.

Who amongst us, in standing before Northrop Auditorium, on raising his eyes to read that inscribed inscription, has not felt a warm glow and a quickening of his emotions.¹²

"The University of Minnesota
Founded in the Faith that Men are
Ennobled by Understanding
Dedicated to the Advancement of Learning
and the Search for Truth
Devoted to the Instruction of Youth and
the Welfare of the State"

Your teachers, parents, wives and husbands will want to join me now, I know, in saying to you in unison with a resounding voice: Well done and Bon Voyage!

Power

In the struggle for power there is no middle course between the highest elevation and the abyss of destruction.—Tacitus

FIGHTING CANCER WITH FILMS...

...is not news. What's news is that we've embarked on the most ambitious film program *for professional medical audiences* ever launched against a single disease. A half-million dollar film project is underway—with technical advice from the nation's leading medical authorities.

Five of these films are available now—

CANCER IN CHILDREN, DIAGNOSIS AND MANAGEMENT OF CANCER OF THE COLON AND RECTUM, ORAL CANCER, NURSING MANAGEMENT OF THE PATIENT WITH CANCER, and THE DENTIST AND CANCER. The balance will be released in 1967-1968.

As pioneers in the usage of medical films, we know their value as teaching tools. Our Units across the country know, too. Films are a vital part of their professional educational programs. We hope you will contact *your* local ACS Unit about this outstanding new series.

This pain is getting on my nerves.

Patients in pain often experience concomitant anxiety and tension, which may add to the burden of pain.

For such patients, you may want to prescribe a preparation that offers more than simple analgesia.

A good choice is often EQUAGESIC® (meprobamate and ethoheptazine citrate with aspirin). It helps relieve pain. And anxiety. And skeletal muscle spasm as related to pain or anxiety and tension.

Equagesic® TABLETS

(meprobamate and ethoheptazine
citrate with aspirin)

Contraindications: History of sensitivity or severe intolerance to aspirin or meprobamate.

Warnings: USE IN PREGNANCY: Safety for use during pregnancy or lactation has not been established; therefore it should be used in pregnant patients or women of child-bearing age only when the physician judges its use essential to the patient's welfare.

Precautions: Keep out of reach of children. Not recommended for patients 12 years old or less. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate may result in dependence or habituation in susceptible persons—as alcoholics, ex-addicts, severe psychoneurotics. Withdraw gradually after prolonged high dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance. If drowsiness, ataxia or visual disturbances (impairment of accommodation and visual acuity) occur, reduce dose. If symptoms persist, caution patients against operating machinery or driving. After meprobamate overdose, prompt sleep, reduction of blood pressure, pulse and respiratory rates to basal levels, and hyperventilation are reported. Give cautiously to patients with suicidal tendencies. Treat attempted suicide (has resulted in coma, shock, vasomotor and respiratory collapse and anuria) with immediate gastric lavage and appropriate supportive therapy (CNS stimulants and pressor amines as indicated).

Side Effects: Ethoheptazine and aspirin may occasionally cause nausea, vomiting, epigastric distress, and rarely dizziness. Overdosage may result in CNS depression (drowsiness and lightheadedness) or CNS stimulation and salicylate intoxication (requires induced vomiting or gastric lavage, specific parenteral electrolyte therapy for ketoacidosis and dehydration, and observation for hypoprothrombinemic hemorrhage [usually requires whole blood transfusions]). Meprobamate may cause drowsiness, ataxia and rarely allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angio-neurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically such as with epinephrine, antihistamine and possibly hydrocortisone. A few cases of leucopenia, usually transient, have been reported following continuous use. Rarely, cases of aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported; almost always, in the presence of known toxic agents.

Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.

Wyeth Laboratories Philadelphia, Pa.

when bursitis hits a 280-lb. tackle, hit back with Butazolidin alka

Indications: Osteoarthritis, rheumatoid arthritis, rheumatoid spondylitis, psoriatic arthritis, acute gout, painful shoulder (peritendinitis, capsulitis, bursitis and acute arthritis of that joint), acute superficial thrombophlebitis.

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently. Large doses of Butazolidin alka are contraindicated in glaucoma.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make regular blood counts. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ul-

For 280-lb. tackles — or 108-lb. housewives — Butazolidin alka can hasten recovery from the agonizing pain of shoulder bursitis.

It's not for every patient. Check carefully the Contraindications, Warning and Precautions shown below.

And adverse reactions may occur. The most common are nausea, edema and rash. Rarely, agranulocytosis has been reported. All adverse reactions are listed below, too.

Play-for-pay or workaday patients — when they come up with shoulder bursitis and your clinical judgment indicates Butazolidin alka — go with it.

And watch the comeback.

cer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately before or after meals or with milk to minimize gastric upset. Mild drug rashes frequently subside with reduction of dosage. However, rash accompanied by fever or other systemic reactions usually requires withholding medication. Purpuric rash has also been reported. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, or a generalized allergic reaction similar to serum sickness may occur and require permanent withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

6509-V(B)R2

Butazolidin[®] alka

Capsules

100 mg. phenylbutazone
100 mg. dried aluminum hydroxide gel
150 mg. magnesium trisilicate
1.25 mg. homatropine methylbromide

Dosage in painful shoulder: Initial: 3 to 6 capsules daily in 3 or 4 equal doses. Trial period: 1 week. Maintenance dosage should not exceed 4 capsules daily; response is often achieved with 1 or 2 capsules daily.

For complete details, please see full prescribing information.

Geigy Pharmaceuticals
Division of Geigy Chemical Corporation, Ardsley, New York

Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by
absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-

mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

aged and debilitated

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Geroniazol[®] TT

nicotinic acid 150 mg., pentylenetetrazol 300 mg.
Tempotrol[®] Time Controlled Tablet

FREO, BY SAUNDERS SCHULTZ

FREE YOUR PATIENTS from
✓ deficient neutralization
✓ poor taste
✓ burdensome cost
with DICARBOSIL® antacid

■ **effective neutralizing power**—Two tablets in vitro¹, provide nearly 2 hours' relief within effective pH range 3 to 5.5.

■ **pleasant taste**—A fresh mint flavor patients continue to enjoy. With Dicarbosil's unique* formulation, chalky after taste is no longer a problem.

■ **exceptional economy**—Due to its high neutralization capacity combined with low cost (about 1¢ or less per tablet), Dicarbosil is within the reach of all patients.

VALIUM® (diazepam)Roche®

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Infants, patients with history of convulsive disorders, glaucoma or known hypersensitivity to drug.

Warning: Not of value in the treatment of psychotic patients, and should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly or debilitated patients (not more than 1 mg, one or two times daily initially) to preclude ataxia or oversedation, increasing gradually as needed or tolerated. As is true of all CNS-acting drugs, until correct maintenance dosage is established, advise patients against possibly hazardous procedures requiring complete mental alertness or physical coordination. Driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended. If such combination therapy is used, carefully consider individual pharmacologic effects—particularly with known compounds which may potentiate action of Valium (diazepam), such as phenothiazines, barbiturates, MAO inhibitors and other antidepressants. Advise patients against simultaneous ingestion of alcohol or other CNS depressants. Safe use in pregnancy not established. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Observe usual precautions in impaired renal or hepatic function. Periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side Effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances, acute hyperexcited states, hallucinations); changes in EEG patterns during and after drug treatment. Abrupt cessation after prolonged overdosage may produce withdrawal symptoms (convulsions, tremor, abdominal and muscle cramps, vomiting, sweating) similar to those seen with barbiturates, meprobamate and chlordiazepoxide HCl.

Dosage—Adults: Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 to 10 mg t.i.d. or q.i.d. *Geriatric patients:* 1 or 2 mg/day initially, increase gradually as needed and tolerated. (See Precautions)

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 50 and 500.

The Arthritis Foundation salutes the thousands of dedicated physicians who volunteer their services in the nation's fight against crippling arthritis.

The Arthritis Foundation is the sole national voluntary health agency committed to conquering the rheumatic diseases. It provides the means for dynamic partnership between physicians and laymen to marshal leadership and resources toward the solution of this major national health problem.

The Arthritis Foundation looks forward to rapid growth with increasing opportunity for physicians to participate in the arthritis movement. For further information about The Arthritis Foundation and its programs write to the Foundation chapter in your community or to the Medical Department, Box 2525, New York, N.Y. 10001.

Diagnosics

Medical Management of Muscular Dystrophy*

PROGRESSIVE MUSCULAR DYSTROPHY is a disease that causes muscle atrophy in young children, usually boys. If you have a muscular dystrophy patient, perhaps your diagnosis wasn't made until the child was three, four, or even seven years old—when his parents noticed an increasing clumsiness running or climbing stairs.

At first his little clumsiness was probably passed off: "Let your son develop according to his own growth. I have checked him, and find nothing wrong. You know, it takes a while for each child to develop his co-ordination and skill level—don't worry, every child is different."

But the parents do worry, and as the progressive weakness becomes more evident, so do you. The child's calves are hypertrophied, he walks on his toes, and to get up from a sitting position he 'climbs up his legs.' Serum enzyme analysis reveals elevated LDH, CPK, and aldolase levels. The diagnosis is made: Duchenne's progressive muscular dystrophy.

The course of the disease is well known. The atrophy advances from the musculature of the hips and shoulders to the extremities, and by early adulthood the child—with severe contractures and an inadequate vital chest capacity—is an invalid. He will die from a respiratory infection. A common cold will kill him.

You cannot cure the disease, but you can do many things to help the child and his parents.

A child with muscular dystrophy learns early that he is failing. He knows that yesterday he could climb the stairs—today he is having trouble. Repeated failure is as defeating to a child as it is to an adult. You know his need for accomplishment—to function on his own—to grow emotionally, mentally, and socially. The child must be somewhat independent.

But, do the parents understand this?

The tendency to over-protect their son is natural, but it will harm him emotionally and physically. You must help these parents expect and insist on capacity performance from the child, for anything less will hasten the disease process. Encourage them to provide love and understanding, not pity, and to respect the youth's desire for independence.

The child's wishes and needs for independence can be met with physical therapy that will maintain his mobility. Joint mobility, the most essential aspect of your treatment, can be preserved or restored with normal range of motion exercises—by moving the body parts through the normal full range possible.

These exercises, if done several times a day, can prevent contractures and deformity. Prescribed with breathing exercises, normal range of motion methods will help maintain vital lung capacity and lower the threat of respiratory infections.

Your patient can do many of these exercises himself, and by experiencing the thrill of achievement and approval, grow in self-respect and confidence.

However, the exercise routine must not be too strenuous. The therapeutic rationale is to keep the child working at his capacity, but not to overtax his resources. The exercises you prescribe and the result will of course depend on the child's condition. How vigorous a program you prescribe will be based on your own common sense and professional judgment, for if the child is over-protected, he will

*Supported in part by the Vocational Rehabilitation Administration Research and Training Grant 2, Department of Health, Education and Welfare, Washington, D. C.

Continued

'go down hill;' on the other hand, if he is overworked, he will also 'go down hill.' The key phrase is 'to his capacity.'

The sooner a daily routine of exercise is established, the more successful will be the treatment. The child will be happier and healthier. His whole body will function better—his circulation (ischemic ulcers will be decreased or eliminated), his digestion (including urinary tract functions) and his respiration.

If the child becomes ill, antibiotics are the treatment of choice, but bed rest must be forbidden unless absolutely necessary, as bed rest can hasten the progress of muscular dystrophy. Dr. Frederic Kottke at the University of Minnesota reports a three percent muscle strength loss per day of total inactivity for normal muscle.
